MIXIM

SOT23, Low-Power µP Supervisory Circuits with Battery Backup and Chip-Enable Gating

General Description

The MAX6365-MAX6368 supervisory circuits simplify power-supply monitoring, battery-backup control functions, and memory write protection in microprocessor (µP) systems. The circuits significantly improve the size, accuracy, and reliability of modern systems with an ultrasmall integrated solution.

These devices perform four basic system functions:

- 1) Provide a µP reset output during VCC supply powerup, power-down, and brownout conditions.
- 2) Internally control VCC to backup-battery switching to maintain data or low-power operation for CMOS RAM, CMOS µPs, real-time clocks, and other digital logic when the main supply fails.
- 3) Provide memory write protection through internal chip-enable gating during supply or processor faults.
- 4) Include one of the following options: a manual reset input (MAX6365), a watchdog timer function (MAX6366), a battery-on output (MAX6367), or an auxiliary user-adjustable reset input (MAX6368).

The MAX6365-MAX6368 operate from VCC supply voltages as low as 1.2V. The factory preset reset threshold voltages range from 2.32V to 4.63V (see Ordering Information). In addition, each part is offered in three reset output versions: push-pull active low, open-drain active low, or open-drain active high (see Selector Guide). The MAX6365-MAX6368 are available in miniature 8-pin SOT23 packages.

Applications

Critical uP/uC Power Monitoring

Fax Machines

Industrial Control

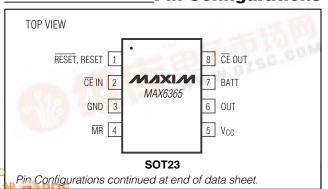

EAXIVI

Computers/Controllers

Portable/Battery-Powered Equipment Set-Top Boxes

Pin Configurations

POS Equipment

Features

- ◆ Low +1.2V Operating Supply Voltage (VCC or VBATT)
- ◆ Precision Monitoring of +5.0V, +3.3V, +3.0V, and +2.5V Power-Supply Voltages
- On-Board Gating of Chip-Enable Signals, 1.5ns **Propagation Delay**
- **Debounced Manual Reset Input (MAX6365)**
- Watchdog Timer, 1.6s Timeout (MAX6366)
- **Battery-On Output Indicator (MAX6367)**
- Auxiliary User-Adjustable RESET IN (MAX6368)
- ♦ Low 10µA Quiescent Supply Current
- ♦ Three Available Output Structures

Push-Pull RESET Open-Drain RESET Open-Drain RESET

- ♦ RESET/RESET Valid Down to 1.2V Guaranteed (VCC or VBATT)
- ♦ Power-Supply Transient Immunity
- 150ms min Reset Timeout Period
- Miniature 8-Pin SOT23 Package

MAX6368

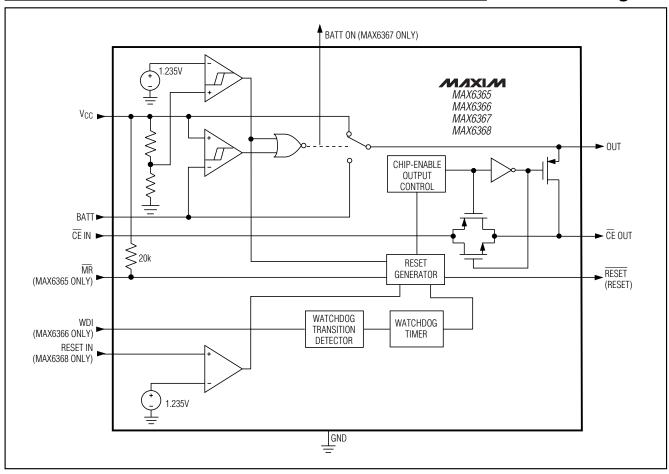

Pin Description

PIN	NAME	FUNCTION
	RESET	Active-High Reset Output. RESET asserts high continuously when V_{CC} is below the reset threshold (V_{TH}), \overline{MR} is low, or RESET IN is low. It asserts in pulses when the internal watchdog times out. RESET remains asserted for the reset timeout period (t_{RP}) after V_{CC} rises above the reset threshold, after the manual reset input goes from low to high, after RESET IN goes high, or after the watchdog triggers a reset event. RESET is an open-drain active-high reset output.
1	RESET	Active-Low Reset Output. RESET asserts low continuously when V _{CC} is below the reset threshold (V _{TH}), the manual reset input is low, or RESET IN is low. It asserts low in pulses when the internal watchdog times out. RESET remains asserted low for the reset timeout period (t _{RP}) after V _{CC} rises above the reset threshold, after the manual reset input goes from low to high, after RESET IN goes high, or after the watchdog triggers a reset event. The MAX636_L is an active-low pushpull output, while the MAX636_P is an active-low open-drain output.
2	CE IN	Chip-Enable Input. The input to chip-enable gating circuitry. Connect to GND or OUT if not used.
3	GND	Ground
	MR	MAX6365 Manual-Reset Input. Maintaining logic low on $\overline{\text{MR}}$ asserts a reset. Reset output remains asserted as long as $\overline{\text{MR}}$ is low and for the reset timeout period (t _{RP}) after $\overline{\text{MR}}$ transitions from low to high. Leave unconnected, or connect to V _{CC} if not used. $\overline{\text{MR}}$ has an internal 20k Ω pullup to V _{CC} .
4	WDI	MAX6366 Watchdog Input. If WDI remains high or low for longer than the watchdog timeout period (twD), the internal watchdog timer runs out and a reset pulse is triggered for the reset timeout period (tRP). The internal watchdog clears whenever reset asserts or whenever WDI sees a rising or falling edge (Figure 2).
	BATT ON	MAX6367 Battery-On Output. BATT ON goes high when in battery backup mode.
	RESET IN	MAX6368 Reset Input. When RESET IN falls below 1.235V, reset asserts. Reset output remains asserted as long as RESET IN is low and for at least the after RESET IN goes high.
5	Vcc	Supply Voltage, 1.2V to 5.5V. Reset asserts when V_{CC} drops below the reset threshold voltage (V _{TH}). Reset remains asserted until V_{CC} rises above V _{TH} and for at least t _{RP} after V_{CC} rises above V _{TH} .
6	OUT	Output. OUT sources from V_{CC} when not in reset and from the greater of V_{CC} or BATT when V_{CC} is below the reset threshold.
7	BATT	Backup-Battery Input. When V_{CC} falls below the reset threshold, OUT switches to BATT if V_{BATT} is 20mV greater than V_{CC} . When V_{CC} rises 20mV above V_{BATT} , OUT switches to V_{CC} . The 40mV hysteresis prevents repeated switching if V_{CC} falls slowly.
8	CE OUT	Chip-Enable Output. $\overline{\text{CE}}$ OUT goes low only when $\overline{\text{CE}}$ IN is low and reset is not asserted. If $\overline{\text{CE}}$ IN is low when reset is asserted, $\overline{\text{CE}}$ OUT will stay low for 12 μ s (typ) or until $\overline{\text{CE}}$ IN goes high, whichever occurs first.

Functional Diagram

Detailed Description

The *Typical Operating Circuit* shows a typical connection for the MAX6365–MAX6368. OUT powers the static random-access memory (SRAM). If VCC is greater than the reset threshold (VTH), or if VCC is lower than VTH but higher than VBATT, VCC is connected to OUT. If VCC is lower than VTH and VCC is less than VBATT, BATT is connected to OUT. OUT supplies up to 150mA from VCC. In battery-backup mode, an internal MOSFET connects the backup battery to OUT. The on-resistance of the MOSFET is a function of backup-battery voltage and is shown in the BATT-to-OUT On-Resistance vs. Temperature graph in the *Typical Operating Characteristics*.

Chip-Enable Signal Gating

The MAX6365–MAX6368 provide internal gating of $\overline{\text{CE}}$ signals to prevent erroneous data from being written to

CMOS RAM in the event of a power failure. During normal operation, the \overline{CE} gate is enabled and passes all \overline{CE} transitions. When reset asserts, this path becomes disabled, preventing erroneous data from corrupting the CMOS RAM. All of these devices use a series transmission gate from \overline{CE} IN to \overline{CE} OUT. The 2ns propagation delay from \overline{CE} IN to \overline{CE} OUT allows the devices to be used with most μPs and high-speed DSPs.

During normal operation, $\overline{\text{CE}}$ IN is connected to $\overline{\text{CE}}$ OUT through a low on-resistance transmission gate. This is valid when reset is not asserted. If $\overline{\text{CE}}$ IN is high when reset is asserted, $\overline{\text{CE}}$ OUT remains high regardless of any subsequent transitions on $\overline{\text{CE}}$ IN during the reset event.

If $\overline{\text{CE}}$ IN is low when reset is asserted, $\overline{\text{CE}}$ OUT is held low for 12 μ s to allow completion of the read/write operation (Figure 1). After the 12 μ s delay expires, the $\overline{\text{CE}}$

OUT goes high and stays high regardless of any subsequent transitions on \overline{CE} IN during the reset event. When \overline{CE} OUT is disconnected from \overline{CE} IN, \overline{CE} OUT is actively pulled up to OUT.

The propagation delay through the chip-enable circuitry depends on both the source impedance of the drive to \overline{CE} IN and the capacitive loading at \overline{CE} OUT. The chip-enable propagation delay is production tested from the 50% point of \overline{CE} IN to the 50% point of \overline{CE} OUT, using a 50 Ω driver and 50pF load capacitance. Minimize the capacitive load at \overline{CE} OUT to minimize propagation delay, and use a low-output-impedance driver.

Backup-Battery Switchover

In a brownout or power failure, it may be necessary to preserve the contents of the RAM. With a backup battery installed at BATT, the MAX6365–MAX6368 automatically switch the RAM to backup power when VCC falls. The MAX6367 has a BATT ON output that goes high in battery-backup mode. These devices require two conditions before switching to battery-backup mode:

- 1) VCC must be below the reset threshold.
- 2) VCC must be below VRATT.

Table 1 lists the status of the inputs and outputs in battery-backup mode. The devices do not power up if the only voltage source is on BATT. OUT only powers up from VCC at startup.

Table 1. Input and Output Status in Battery-Backup Mode

PIN	STATUS
Vcc	Disconnected from OUT
OUT	Connected to BATT
BATT	Connected to OUT. Current drawn from the battery is less than 1μ A (at V_{BATT} = 2.8V, excluding I_{OUT}) when V_{CC} = 0.
RESET/RESET	Asserted
BATT ON	High state
MR, RESET IN, CE IN, WDI	Inputs ignored
CE OUT	Connected to OUT

Manual Reset Input (MAX6365 Only)

Many μP -based products require manual reset capability, allowing the user or external logic circuitry to initiate a reset. For the MAX6365, a logic low on \overline{MR} asserts reset. Reset remains asserted while \overline{MR} is low and for a minimum of 150ms (tRP) after it returns high. \overline{MR} has an internal 20k Ω pullup resistor to VCC. This input can be driven with TTL/CMOS logic levels or with open-drain/collector outputs. Connect a normally open momentary switch from \overline{MR} to GND to create a manual reset function; external debounce circuitry is not required. If \overline{MR} is driven from long cables or the device is used in a noisy environment, connect a 0.1 μF capacitor from \overline{MR} to GND to provide additional noise immunity.

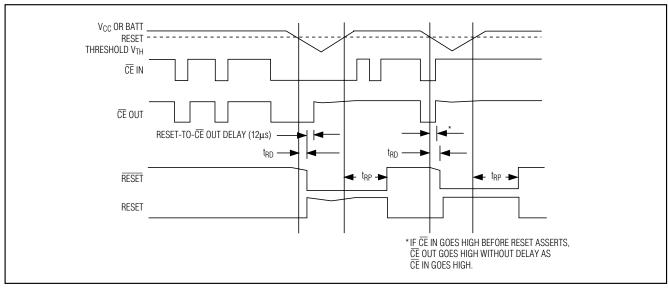

Figure 1. Reset and Chip-Enable Timing

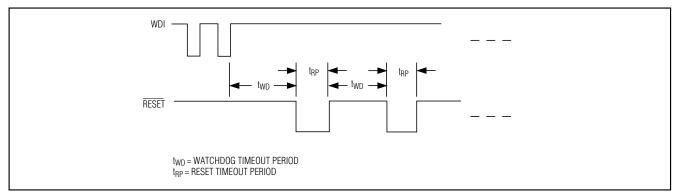

Figure 2. MAX6366 Watchdog Timeout Period and Reset Active Time

Watchdog Input (MAX6366 Only)

The watchdog monitors μP activity through the watchdog input (WDI). If the μP becomes inactive, reset asserts. To use the watchdog function, connect WDI to a bus line or μP I/O line. A change of state (high to low, low to high, or a minimum 100ns pulse) resets the watchdog timer. If WDI remains high or low for longer than the watchdog timeout period (twD), the internal watchdog timer runs out and a reset pulse is triggered for the reset timeout period (tRP). The internal watchdog timer clears whenever reset asserts or whenever WDI sees a rising or falling edge. If WDI remains in either a high or low state, a reset pulse asserts periodically after every twD (Figure 2). Leave WDI unconnected to disable the watchdog function.

BATT ON Indicator (MAX6367 Only)

BATT ON is a push-pull output that drives high when in battery-backup mode. BATT ON typically sinks 3.2mA at 0.1V saturation voltage. In battery-backup mode, this terminal sources approximately 10µA from OUT. Use BATT ON to indicate battery-switchover status or to supply base drive to an external pass transistor for higher current applications (Figure 3).

RESET IN Comparator (MAX6368 Only)

RESET IN is compared to an internal 1.235V reference. If the voltage at RESET IN is less than 1.235V, reset asserts. Use the RESET IN comparator as an undervoltage detector to signal a failing power supply or as a secondary power-supply reset monitor.

To program the reset threshold (V_{RTH}) of the secondary power supply, use the following (see *Typical Operating Circuit*):

$$V_{RTH} = V_{REF} (R1 / R2 + 1)$$

where V_{REF} = 1.235V. To simplify the resistor selection, choose a value for R2 and calculate R1:

$R1 = R2 [(V_{RTH} / V_{REF}) - 1]$

Since the input current at RESET IN is 25nA (max), large values (up to $1M\Omega$) can be used for R2 with no significant loss in accuracy. For example, in the *Typical Operating Circuit*, the MAX6368 monitors two supply voltages. To monitor the secondary 5V logic or analog supply with a 4.60V nominal programmed reset threshold, choose R2 = $100k\Omega$, and calculate R1 = $273k\Omega$.

Reset Output

A µP's reset input starts the µP in a known state. The MAX6365–MAX6368 µP supervisory circuits assert a reset to prevent code-execution errors during power-up, power-down, and brownout conditions. RESET is guaranteed to be a logic low or logic high, depending on the device chosen (see *Ordering Information*). RESET or RESET asserts when VCC is below the reset threshold and for at least 150ms (tRP) after VCC rises above the reset threshold. RESET or RESET also asserts when $\overline{\text{MR}}$ is low (MAX6365) and when RESET IN is less than 1.235V (MAX6368). The MAX6366 watch-dog function will cause RESET (or RESET) to assert in pulses following a watchdog timeout (Figure 2).

_Applications Information

Operation Without a Backup Power Source

The MAX6365–MAX6368 provide battery-backup functions. If a backup power source is not used, connect BATT to GND and OUT to $V_{\rm CC}$.

Watchdog Software Considerations

One way to help the watchdog timer monitor the software execution more closely is to set and reset the watchdog at different points in the program rather than pulsing the watchdog input periodically. Figure 4 shows a flow diagram in which the I/O driving the

watchdog is set low in the beginning of the program, set high at the beginning of every subroutine or loop, and set low again when the program returns to the beginning. If the program should hang in any subroutine, the problem would be quickly corrected.

Replacing the Backup Battery

When V_{CC} is above V_{TH}, the backup power source can be removed without danger of triggering a reset pulse. The device does not enter battery-backup mode when V_{CC} stays above the reset threshold voltage.

Negative-Going V_{CC} Transients

These supervisors are relatively immune to short-duration, negative-going V_{CC} transients. Resetting the μP when V_{CC} experiences only small glitches is usually not desirable.

The *Typical Operating Characteristics* section has a Maximum Transient Duration vs. Reset Threshold Overdrive graph for which reset is not asserted. The graph was produced using negative-going V_{CC} pulses,

starting at VCC and ending below the reset threshold by the magnitude indicated (reset threshold overdrive). The graph shows the maximum pulse width that a negative-going VCC transient can typically have without triggering a reset pulse. As the amplitude of the transient increases (i.e., goes further below the reset threshold), the maximum allowable pulse width decreases. Typically, a VCC transient that goes 100mV below the reset threshold and lasts for 30µs will not trigger a reset pulse.

A $0.1\mu F$ bypass capacitor mounted close to the V_{CC} pin provides additional transient immunity.

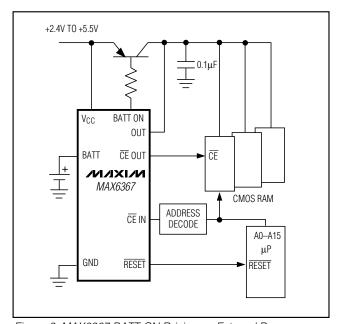

Figure 3. MAX6367 BATT ON Driving an External Pass Transistor
