

## AUDIO CODEC WITH INTEGRATED HEADPHONE, SPEAKER AMPLIFIER AND TOUCH SCREEN CONTROLLER

### FEATURES

- Stereo Audio Playback Up to 48 ksp/s
- Mono Audio Record up to 48 ksp/s
- Integrated PLL for Audio Clock Generation
- Programmable Gain Amplifiers
- Hardware Automatic Gain Control
- Programmable Digital Audio Effects Processing
- Stereo Headset Interface
- Cellular Headset Interface
- 8-Ω Speaker Driver
- 32-Ω Receiver Driver
- Interface with Microphone
- Auto-Detection of Headset and Button Press
- Supports Both Cap and Cap-Less Interface for Headset
- Programmable Audio Routing
- 4-Wire Touch Screen Interface
- Integrated Touch Screen Processor With Fully Automated Modes of Operation
- Programmable Converter Resolution, Speed, and Averaging
- Programmable Autonomous Timing Control
- Direct Battery Measurement
- Built-In Buffer for Touch Screen Data
- SPI™ Serial Interface
- Low Power
- Full Power-Down Control
- 48-Pin QFN Package

### APPLICATIONS

- Personal Digital Assistants
- Smart Cellular Phones
- MP3 Players

### DESCRIPTION

The TSC2101 is a low-power highly integrated high performance codec and touch screen controller, which supports stereo audio DAC, mono audio ADC and SAR ADC.

The TSC2101 features a high-performance audio codec with 16, 20, 24, or 32-bit stereo playback, mono record functionality at up to 48 ksp/s. The device integrates several analog features such as support for headset interface, cellular headset interface, microphone interface, and speaker and receiver drivers. The device supports auto detection of headset and button press without any glue logic. The TSC2101 has fully programmable audio. The digital audio data format is programmable to work with popular audio standard protocols (I2S, DSP, left/right justified) in master or slave mode, and also includes an on-chip PLL for flexible clock generation capability.

The TSC2101 contains a 12-bit 4-wire resistive touch screen converter complete with drivers, and interfaces to the host controller through a standard SPI™ serial interface. The on-chip processor provides extensive features specifically designed to reduce host processor and bus overhead, with capabilities that include fully automated operating modes, programmable conversion resolution up to 12 bits, programmable sampling rates up to 125 kHz, programmable conversion averaging, and programmable on-chip timing generation.

The TSC2101 offers battery measurement inputs capable of reading battery voltages up to 6 V, while operating at only 3 V. It also has an on-chip temperature sensor capable of reading 0.3°C resolution. The TSC2101 is available in a 48-lead QFN.

US Patent No. 6246394

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

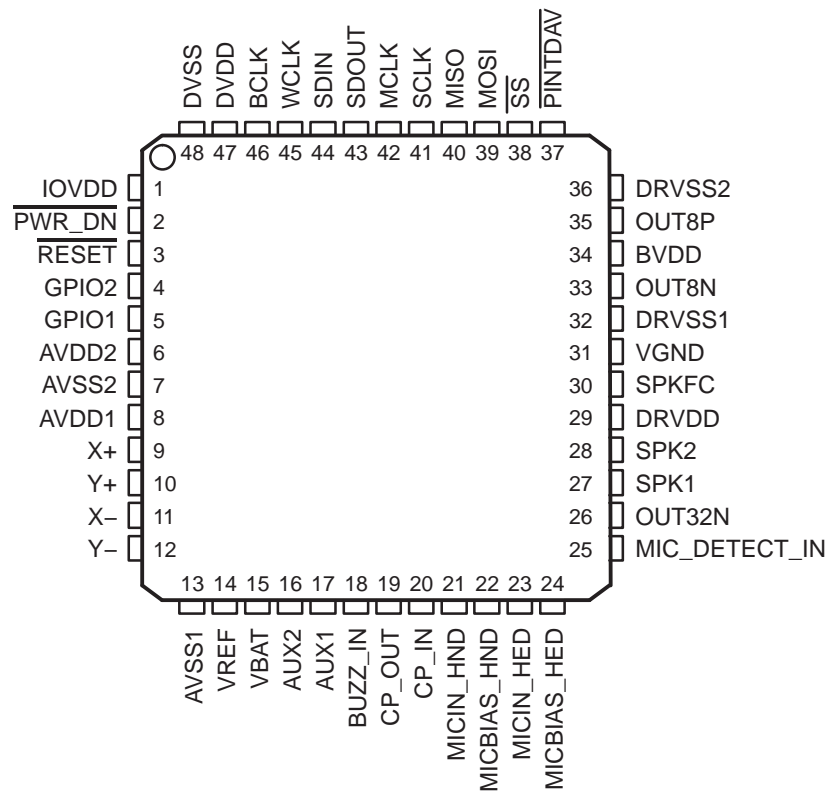

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

**PACKAGE/ORDERING INFORMATION**

### ABSOLUTE MAXIMUM RATINGS

over operating free-air temperature range unless otherwise noted<sup>(1), (2)</sup>

|   | UNITS  |  |
|---|--|--|
| AVDD1/2 to AVSS1/2                            | –0.3 V to 3.9 V  |  |
| DRVDD to DRVSS1/2                             | –0.3 V to 3.9 V  |  |
| BVDD to DRVSS1/2                              | –0.3 V to 4.5 V  |  |
| IOVDD to DVSS                                 | –0.3 V to 3.9 V  |  |
| Digital input voltage to DVSS                 | –0.3 V to IOVDD + 0.3 V  |  |
| Analog input (except VBAT) voltage to AVSS1/2 | –0.3 V to AVDD + 0.3 V   |  |
| VBAT input voltage to AVSS1/2                 | –0.3 V to 6 V  |  |
| AVSS1/2 to DRVSS1/2 to DVSS                   | –0.1 V to 0.1 V  |  |
| AVDD1/2 to DRVDD                              | –0.1 V to 0.1 V  |  |
| Operating temperature range                   | –40°C to 85°C  |  |
| Storage temperature range                     | –65°C to 105°C   |  |
| Junction temperature (T <sub>J</sub> Max)     | 105°C  |  |
| QFN package                                   | Power dissipation  | (T <sub>J</sub> Max – T <sub>A</sub> )/θ <sub>JA</sub> |
|   | θ <sub>JA</sub> Thermal impedance (with thermal pad soldered to board) | 27°C/W   |
| Lead temperature                              | Infrared (15 sec)  | 240°C  |

<sup>(1)</sup> Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

<sup>(2)</sup> If the TSC2101 is used to drive high power levels to an 8-Ω load for extended intervals at an ambient temperature above 80°C, multiple vias should be used to electrically and thermally connect the thermal pad on the QFN package to an internal heat dissipating ground plane on the user’s PCB.

**ELECTRICAL CHARACTERISTICS**At +25°C, AVDD1, AVDD2, DRVDD, IOVDD = 3.3 V, BVDD = 3.9 V, DVDD = 1.8 V, V<sub>ref</sub> = 2.5 V, Fs (Audio) = 48 kHz, unless otherwise noted

(1) ADC PSRR measurement is calculated as:

$$PSRR = 20 \log_{10} \left( \frac{V_{SIG_{sup}}}{V_{ADCOUT}} \right)$$

 where V<sub>SIG<sub>sup</sub></sub> is the ac signal applied on AVDD1/2, which is 100 mV<sub>pp</sub> at 1020 Hz, and  $V_{ADCOUT} = \frac{\text{Amplitude of Digital Output}}{\text{Max Possible Digital Amplitude}}$

**ELECTRICAL CHARACTERISTICS (continued)**

At +25°C, AVDD1, AVDD2, DRVDD, IOVDD = 3.3 V, BVDD = 3.9 V, DVDD = 1.8 V, V<sub>ref</sub> = 2.5 V, Fs (Audio) = 48 kHz, unless otherwise noted (continued)

## OVERVIEW

The TSC2101 is a highly integrated stereo audio DAC and mono audio ADC with touch screen controller for portable computing, communication and entertainment applications. A register-based architecture eases integration with microprocessor-based systems through a standard SPI bus. All peripheral functions are controlled through the registers and on-board state machines.

The TSC2101 consists of the following blocks:

- Audio Codec
- Headset and Button Detection
- Touch Screen Interface
- Battery Monitors
- Auxiliary Inputs
- Temperature Monitor

Communication to the TSC2101 is via a standard SPI serial interface. This interface requires that the Slave Select signal ( $\overline{SS}$ ) be driven low to communicate with the TSC2101. Data is then shifted into or out of the TSC2101 under control of the host microprocessor, which also provides the serial data clock.

Control of the TSC2101 and its functions is accomplished by writing to different registers in the TSC2101. A simple command protocol is used to address the 16-bit registers. Registers control the operation of the SAR ADC and audio codec.

## OPERATION—AUDIO CODEC

### AUDIO ANALOG I/O

The TSC2101 has stereo audio DAC and mono audio ADC. It supports a wide range of analog interface to support different headsets and analog outputs. The TSC2101 has features to interface output drivers (8- $\Omega$ , 16- $\Omega$ , 32- $\Omega$ ) and Microphone PGA to Cell-phone. The TSC2101 also has a virtual ground (VGND) output, which can be optionally used to connect to the ground terminal of a speaker or headphone to eliminate the ac-coupling capacitor needed at the speaker or headphone output. A special circuit has also been included in the TSC2101 to insert a short keyclick sound into the stereo audio output, even when the audio DAC is powered down. The keyclick sound is used to provide feedback to the user when a particular button is pressed or item is selected. The specific sound of the keyclick can be adjusted by varying several register bits that control its frequency, duration, and amplitude.

### AUDIO DIGITAL I/O INTERFACE

Digital audio data samples can be transmitted between the TSC2101 and the CPU via the serial bus (BCLK, WCLK, SDO<sub>OUT</sub>, SDIN) that can be configured to transfer digital data in four different formats: Right justified (RJF), Left justified (LJF), I<sup>2</sup>S and DSP. The four modes are MSB first and operate with variable word length between 16/20/24/32 bits. The TSC2101's audio codec can operate in master or slave mode, depending on its register settings. The word-select signal (WCLK) and bit clock signal (BCLK) are configured as outputs when the bus is in master mode. They are configured as inputs when the bus is in slave mode. The WCLK is representative of the sampling rate of the audio ADC/DAC and is synchronized with SDO<sub>OUT</sub>. Although the SDO<sub>OUT</sub> signal can contain two channels of information (a left and right channel), the TSC2101 sends the same ADC data in both channels.

- **ADC/DAC Sampling Rate**

The audio-control-1 register (Register 00H, Page 2) determines the sampling rates of DAC and ADC. The sampling frequency is scaled down from the reference rate (Fsref). The reference rate is usually either 44.1 kHz or 48 kHz which can be selectable using bit D13 of the register Audio Control 3 (06H/Page2). The ADC and DAC can operate with either common WCLK (equal sampling rates) or separate GPIO1 (For ADC) and WCLK (For DAC) for unequal sampling rates. When the audio codec is powered up, it is by default configured as an I<sup>2</sup>S slave with both the DAC and ADC operating at Fsref.

- **Word Select Signals**

The word select signal (WCLK) indicates the channel being transmitted:

- WCLK = 0: left channel for I<sup>2</sup>S mode;
- WCLK = 1: right channel for I<sup>2</sup>S mode.

For other modes refer to the timing diagrams below.

- **Bitclock (BCLK) Signal**

In addition to being programmable as master or slave mode, the BCLK can also be configured in two transfer modes, 256-S transfer mode and continuous transfer mode, which are described below. These modes are set using bit D12 of control register 06H/page 2.

- **256-S Transfer Mode**

In the 256-S mode, the BCLK rate always equals 256 times the WCLK frequency. In the 256-S mode, the combination of ADC/DAC sampling rate equal to  $F_{sref}$  (as selected by bit D5D0 of control register 00H/page 2) and left-justified mode is not supported. If IOVDD is equal to 1.1 V, then ADC/DAC sampling rate should be less than 39 kHz for all modes except the left justified mode where it should be less than 24 kHz.

- **Continuous Transfer Mode**

In the continuous transfer mode, the BCLK rate always equals two-word length times the frequency of WCLK.

- **Right Justified Mode**

In right-justified mode, the LSB of left channel is valid on the rising edge of BCLK preceding, the falling edge on WCLK. Similarly the LSB of right channel is valid on the rising edge of BCLK preceding the rising edge of WCLK.

**Figure 15. Timing Diagram for Right-Justified Mode**

● **Left Justified Mode**

In left-justified mode, the MSB of right channel is valid on the rising edge of BCLK, following the falling edge on WCLK. Similarly the MSB of left channel is valid on the rising edge of BCLK following the rising edge of WCLK.

Figure 16. Timing Diagram for Left-Justified Mode

● **I<sup>2</sup>S Mode**

In I<sup>2</sup>S mode, the MSB of left channel is valid on the second rising edge of BCLK, after the falling edge on WCLK. Similarly the MSB of right channel is valid on the second rising edge of BCLK, after the rising edge of WCLK.

Figure 17. Timing Diagram for Right-Justified Mode

● **DSP Mode**

In DSP mode, the falling edge of WCLK starts the data transfer with the left channel data first and immediately followed by the right channel data. Each data bit is valid on the falling edge of BCLK.

Figure 18. Timing Diagram for DSP Mode

## AUDIO DATA CONVERTERS

The TSC2101 includes a stereo audio DAC and a mono audio ADC. Both ADC and DAC can operate with a maximum sampling rate of 53 kHz and support all audio standard rates of 8 kHz, 11.025 kHz, 12 kHz, 16 kHz, 22.05 kHz, 24 kHz, 32 kHz, 44.1 kHz, and 48 kHz. By utilizing the flexible clock generation capability and internal programmable interpolation, a wide variety of sampling rates up to 53 kHz can be obtained from many possible MCLK inputs. In addition, the DAC and ADC can independently operate at different sampling rates as indicated in control register 00H/page 2.

When the ADC or DAC is operating, the TSC2101 requires an applied audio MCLK input. The user should also set bit D13 of control register 06H/page 2 to indicate which Fsref rate is being used. If the codec ADC or DAC is powered up, then the touch screen ADC uses MCLK and BCLK for its internal clocking, and the internal oscillator is powered down to save power.

Typical audio DACs can suffer from poor out-of-band noise performance when operated at low sampling rates, such as 8 kHz or 11.025 kHz. The TSC2101 includes programmable interpolation circuitry to provide improved audio performance at such low sampling rates, by first upsampling low-rate data to a higher rate, filtering to reduce audible images, and then passing the data to the internal DAC, which is actually operating at the Fsref rate. This programmable interpolation is determined using bit D5D3 of control register 00H/page 2.

For example, if playback of 11.025 kHz data is required, the TSC2101 can be configured such that Fsref = 44.1 kHz. Then using bit D5D3 of control register/page 2, the DAC sampling rate (Fs) can be set to Fsref/4, or FS = 11.025 kHz. In operation, the 11.025 kHz digital input data is received by the TSC2101, upsampled to 44.1 kHz, and filtered for images. It is then provided to the audio DAC operating at 44.1 kHz for playback. In reality, the audio DAC further upsamples the 44.1 kHz data by a ratio of 128 x and performs extensive interpolation filtering and processing on this data before conversion to a stereo analog output signal.

### Phase Locked Loop (PLL)

The TSC2101 has an on chip PLL to generate the needed internal ADC and DAC operational clocks from a wide variety of clocks that may be available in the system. The PLL supports an MCLK varying from 2 MHz to 100 MHz and is register programmable to enable generation of required sampling rates with fine precision.

ADC and DAC sampling rates are given by

$$\text{DAC}_{Fs} = \frac{\text{Fsref}}{N1}$$

and

$$\text{ADC}_{Fs} = \frac{\text{Fsref}}{N2}$$

Where, Fsref must fall between 39 kHz and 53 kHz, and N1, N2=1, 1.5, 2, 3, 4, 5, 5.5, 6 are register programmable.

The PLL can be enabled or disabled using register programming.

- When PLL is disabled

$$\text{Fsref} = \frac{\text{MCLK}}{128 \times Q}$$

$$Q = 2, 3 \dots 17$$

— Note: For ADC, with N2 = 1.5 or 5.5, odd values of Q are not allowed.

— In this mode, the MCLK can operate up to 100 MHz, and Fsref should fall between 39 kHz and 53 kHz.

- When PLL is enabled

$$F_{sref} = \frac{MCLK \times K}{2048 \times P}$$

$$P = 1, 2, 3 \dots 8$$

$$K = J.D$$

$$J = 1, 2, 3 \dots 64$$

$$D = 0, 1, 2 \dots 9999$$

P, J and D are register programmable. where J is integer part of K before the decimal point, and D is four-digit fractional part of K after the decimal point, including lagging zeros.

Examples: If K = 8.5, then J = 8, D = 5000

If K = 7.12, then J = 7, D = 1200

If K = 7.012, then J = 7, D = 120

The PLL is programmed through Registers 1BH and 1CH of Page 2.

- When PLL is enabled and D = 0, the following conditions must be satisfied

$$2 \text{ MHz} \leq \frac{MCLK}{P} \leq 20 \text{ MHz}$$

$$80 \text{ MHz} \leq \frac{MCLK \times K}{P} \leq 110 \text{ MHz}$$

$$4 \leq J \leq 55$$

- When PLL is enabled D ≠ 0, the following conditions must be satisfied

$$10 \text{ MHz} \leq \frac{MCLK}{P} \leq 20 \text{ MHz}$$

$$80 \text{ MHz} \leq \frac{MCLK \times K}{P} \leq 110 \text{ MHz}$$

$$4 \leq J \leq 11$$

#### Example 1:

For MCLK = 12 MHz and Fsref = 44.1 kHz

P = 1, K = 7.5264

J = 7, D = 5264

#### Example 2:

For MCLK = 12 MHz and Fsref = 48 kHz

P = 1, K = 8.192

J = 8, D = 1920

## MONO AUDIO ADC

### Analog Front End

The analog front end of the audio ADC consists of an analog MUX and a programmable gain amplifier (PGA). The MUX can connect either of the Headset Input (MICIN\_HED), Handset Input (MICIN\_HND), AUX1 and AUX2 signal through the PGA to the ADC for audio recording. The Cell-phone Input (CP\_IN) can also be connected to ADC through a PGA at the same time. This enables recording of conversation during a cell-phone call. The TSC2101 also has an option of choosing MICIN\_HED/MICIN\_HND and AUX1/AUX2 as differential input pair. The TSC2101 also includes two microphone bias circuits which can source up to 5 mA of current, and are programmable to a 2 V, 2.5 V or 3.3 V level for Headset and 2 V or 3.3 V level for handset.

Because of the oversampling nature of the audio ADC and the integrated digital decimation filtering, requirements for analog anti-aliasing filtering are very relaxed. The TSC2101 integrates a second order analog anti-aliasing filter with 20-dB attenuation at 1 MHz. This filter, combined with the digital decimation filter, provides sufficient anti-aliasing filtering without requiring any external components.

The PGA, for microphone and AUX Inputs, allows analog gain control from 0 dB to 59.5 dB in steps of 0.5 dB. The PGA gain changes are implemented with an internal soft-stepping. This soft-stepping ensures that volume control changes occur smoothly with no audible artifacts. Upon reset, the PGA gain defaults to a mute condition, and upon power down, the PGA soft-steps the volume to mute before shutting down. A read-only flag (D0 control register 04H/Page 2) is set whenever the gain applied by PGA equals the desired value set by the register. The soft-stepping control can be disabled by programming D15=1 in register 1DH of Page 2. When soft stepping is enabled and ADC power down register is written, MCLK should be running to ensure that soft-stepping to mute has completed. MCLK can be shut down once Mic PGA power down flag is set.

The PGA, for Cell phone Input (CP\_IN) allows gain control from –34.5 dB to 12 dB in steps of 0.5 dB. The PGA gain changes are implemented with an internal soft-stepping. This soft-stepping ensures that volume control changes occur smoothly with no audible artifacts. Upon reset, the PGA gain defaults to a mute condition, and upon power down, the PGA soft-steps the volume to mute before shutting down. A read-only flag (D7 control register 1FH/Page 2) is set whenever the gain applied by PGA equals the desired value set by the register. The soft-stepping control can be disabled by the programming D12=1 in register 1DH of Page 2. When soft-stepping is enabled and ADC power down register is written, MCLK should be running to ensure that soft-stepping to mute has completed. MCLK can be shut down once Cell PGA power down flag is set.

### Delta-Sigma ADC

The analog-to-digital converter has a delta-sigma modulator with a 128 times oversampling ratio. The ADC can support maximum output rate of 53 kHz.

### Decimation Filter

The audio ADC includes an integrated digital decimation filter that removes high frequency content and downsamples the audio data from an initial sampling rate of 128 times  $F_s$  to the final output sampling rate of  $F_s$ . The decimation filter provides a linear phase output response with a group delay of  $17/F_s$ . The –3 dB bandwidth of the decimation filter extends to  $0.45 F_s$  and scales with the sample rate ( $F_s$ ).

### Programmable High Pass Filter

The ADC channel has a programmable high-pass filter whose cutoff frequency can be programmed through control register. By default the high pass filter is off. The high-pass filter is a first order IIR filter. This filter can be used to remove the DC component of the input signal and offset of the ADC channel.

### Automatic Gain Control (AGC)

The TSC2101 includes Automatic gain control (AGC) for Microphone Inputs (MICIN\_HED or MICIN\_HND) and Cell-phone input (CP\_IN). AGC can be used to maintain nominally constant output signal amplitude when recording speech signals. This circuitry automatically adjusts the PGA gain as the input signal becomes overly loud or very weak, such as when a person speaking into a microphone moves closer or farther from the microphone. The AGC algorithm has several programmable settings, including target gain, attack and decay time constants, noise threshold, and max PGA applicable that allow the algorithm to be fine tuned for any particular application. The algorithm uses the absolute average of the signal (which is the average of the absolute value of the signal) as a measure of the nominal amplitude of the output signal.

**Target gain** represents the nominal output level at which the AGC attempts to hold the ADC output signal level. The TSC2101 allows programming of eight different target gains, which can be programmed from –5.5 dB to –24 dB relative to a full-scale signal. Since the TSC2101 reacts to the signal absolute average and not to peak levels, it is recommended that the target gain be set with enough margin to avoid clipping at the occurrence of loud sounds.

**Attack time** determines how quickly the AGC circuitry reduces the PGA gain when the input signal is too loud. It can be varied from 8 ms to 20 ms.

**Decay time** determines how quickly the PGA gain is increased when the input signal is too low. It can be varied in the range from 100 ms to 500 ms.

**Noise threshold** determines level below which if the input speech average value falls, AGC considers it as a silence and hence brings down the gain to 0 dB in steps of 0.5 dB every FS and sets noise threshold flag. The gain stays at 0 dB unless the input speech signal average rises above noise threshold setting. This ensures

that noise does not get gained up in the absence of speech. Noise threshold level in the AGC algorithm is programmable from  $-30\text{dB}$  to  $-90\text{dB}$  for microphone input, and from  $-30\text{dB}$  to  $-60\text{dB}$  for cell-phone input. When AGC Noise Threshold is set to  $-70\text{dB}$ ,  $-80\text{dB}$ , or  $-90\text{dB}$ , the microphone input Max PGA applicable setting must be greater than or equal to  $11.5\text{dB}$ ,  $21.5\text{dB}$ , or  $31.5\text{dB}$  respectively. This operation includes debounce and hysteresis to avoid the AGC gain from cycling between high gain and  $0\text{dB}$  when signals are near the noise threshold level. When noise threshold flag is set, status of gain applied by AGC and saturation flag should be ignored.

**Max PGA applicable** allows user to restrict maximum gain applied by AGC. This can be used for limiting PGA gain in situations where environment noise is greater than programmed noise threshold. Microphone input Max PGA can be programmed from  $0\text{dB}$  to  $59.5\text{dB}$  in steps of  $0.5\text{dB}$ . Cell-phone input Max PGA can be programmed from  $-34.5\text{dB}$  to  $-0.5\text{dB}$  in steps of  $0.5\text{dB}$ , as well as  $+12\text{dB}$ .

See Table 1 for various AGC programming options. AGC can be used only if microphone input or Cell-phone input is routed to the ADC channel. When both microphone input and Cell-phone input are connected to the ADC, AGC is automatically disabled.

Figure 19. AGC Characteristics

**Table 1. AGC Settings**

|  | MIC HEADSET INPUT |                  | MIC HANDSET INPUT |                  | CELL-PHONE INPUT |                  |

NOTE: All settings shown in Table 1 are located in Page 2 of control registers.

## Stereo Audio DAC

Each channel of the stereo audio DAC consists of a digital audio processing block, a digital interpolation filter, digital delta-sigma modulator, and an analog reconstruction filter. The DAC is designed to provide enhanced performance at low sample rates through increased oversampling and image filtering, thereby keeping quantization noise generated within the delta-sigma modulator and signal images strongly suppressed within the audio band to beyond 20 kHz. This is realized by keeping the upsampled rate constant at 128 x Fsref and changing the oversampling ratio as the input sample rate is changed. For Fsref of 48 kHz, the digital delta-sigma modulator always operates at a rate of 6.144 MHz. This ensures that quantization noise generated within the delta-sigma modulator stays within the frequency band below 20 kHz at all sample rates. Similarly, for Fsref rate of 44.1 kHz, the digital delta-sigma modulator always operates at a rate of 5.6448 MHz.

## Digital Audio Processing

The DAC channel consists of optional filters for de-emphasis and bass, treble, midrange level adjustment, or speaker equalization. The de-emphasis function is only available for sample rates of 32 kHz, 44.1 kHz, and 48 kHz. The transfer function consists of a pole with time constant of 50ms and a zero with time constant of 15ms. Frequency response plots are given in the *Audio Codec Filter Frequency Responses* section of this data sheet.

The DAC digital effects processing block consists of a fourth order digital IIR filter with programmable coefficients (one set per channel). The filter is implemented as cascade of two biquad sections with frequency response given by:

$$\left( \frac{N_0 + 2 \times N_1 \times z^{-1} + N_2 \times z^{-2}}{32768 - 2 \times D_1 \times z^{-1} - D_2 \times z^{-2}} \right) \left( \frac{N_3 + 2 \times N_4 \times z^{-1} + N_5 \times z^{-2}}{32768 - 2 \times D_4 \times z^{-1} - D_5 \times z^{-2}} \right)$$

The N and D coefficients are fully programmable, and the entire filter can be enabled or bypassed. The coefficients for this filter implement a variety of sound effects, with bass-boost or treble boost being the most commonly used in portable audio applications. The default N and D coefficients in the part are given by:

$$\begin{aligned} N_0 &= N_3 = 27619 \\ N_1 &= N_4 = -27034 \\ N_2 &= N_5 = 26461 \\ D_1 &= D_4 = 32131 \\ D_2 &= D_5 = -31506 \end{aligned}$$

These coefficients implement a shelving filter with 0 dB gain from dc to approximately 150 Hz, at which point it rolls off to 3 dB attenuation for higher frequency signals, thus giving a 3-dB boost to signals below 150 Hz. The N and D coefficients are represented by 16-bit twos complement numbers with values ranging from –32768 to +32767. Frequency response plots are given in the *Audio Codec Filter Frequency Responses* section of this data sheet.

### Interpolation Filter

The interpolation filter upsamples the output of the digital audio processing block by the required oversampling ratio. It provides a linear phase output with a group delay of  $21/F_s$ .

In addition, the digital interpolation filter provides enhanced image filtering to reduce signal images caused by the upsampling process that are below 20 kHz. For example, upsampling an 8-kHz signal produces signal images at multiples of 8 kHz, i.e., 8 kHz, 16 kHz, 24 kHz, etc. The images at 8 kHz and 16 kHz are below 20 kHz and still audible to the listener, therefore, they must be filtered heavily to maintain a good quality output. The interpolation filter is designed to maintain at least 65 dB rejection of images that land below  $7.455 F_s$ . In order to utilize the programmable interpolation capability, the  $F_{sref}$  should be programmed to a higher rate (restricted to be in the range of 39 kHz to 53 kHz when the PLL is in use), and the actual  $F_s$  is set using the dividers in bits D5D3 of control register 00H/page 2. For example, if  $F_s = 8$  kHz is required, then  $F_{sref}$  can be set to 48 kHz, and the DAC  $F_s$  set to  $F_{sref}/6$ . This ensures that all images of the 8-kHz data are sufficiently attenuated well beyond a 20-kHz audible frequency range. Passband ripple for all sample-rate cases (from 20 Hz to  $0.45 F_s$ ) is +0.06 dB maximum.

### Delta-Sigma DAC

The audio digital-to-analog converter incorporates a third order multi-bit delta-sigma modulator followed by an analog reconstruction filter. The DAC provides high-resolution, low-noise performance, using oversampling and noise shaping techniques. The analog reconstruction filter design consists of a 6 tap analog FIR filter followed by a continuous time RC filter. The analog FIR operates at 6.144 MHz ( $128 \times 48$  kHz, for  $F_{sref}$  of 48 kHz) or at 5.6448 MHz ( $128 \times 44.1$  kHz, for  $F_{sref}$  of 44.1 kHz). The DAC analog performance may be degraded by excessive clock jitter on the MCLK input. Therefore, care must be taken to keep jitter on this clock to a minimum (less than 50 ps).

### DAC Digital Volume Control

The DAC has a digital volume control block, which implements programmable gain. The volume level can be varied from 0 dB to –63.5 dB in 0.5 dB steps, in addition to a mute bit, independently for each channel. The volume level of both channels can also be changed simultaneously by the master volume control. The gain is implemented with a soft-stepping algorithm, which only changes the actual volume by one step per input sample, either up or down, until the desired volume is reached. The rate of soft-stepping can be slowed to one step per two input samples through D1 of control register 04H/Page 2.

Because of soft-stepping, the host does not know when the DAC has been completely muted. This may be important if the host wishes to mute the DAC before making a significant change, such as changing sample rates. In order to help with this situation, the part provides a flag back to the host via a read-only register bit (D2–D3 of control register 04H/page 2) that alerts the host when the part has completed the soft-stepping, and the actual volume has reached the desired volume level. The soft-stepping feature can be disabled by programming D14=1 in register 1DH in Page 2. If soft-stepping is enabled, the MCLK signal should be kept applied to the device, until the DAC power-down flag is set. When this flag is set, the internal soft-stepping process and power down sequence is complete, and the MCLK can be stopped if desired.

The TSC2101 also includes functionality to detect when the user switches on or off the de-emphasis or digital audio processing functions, then (1) soft-mute the DAC volume control, (2) change the operation of the digital effects processing and (3) soft-unmute the part. This avoids any possible pop/clicks in the audio output due to instantaneous changes in the filtering. A similar algorithm is used when first powering up or down the DAC. The circuit begins operation at power-up with the volume control muted, then soft-steps it up to the desired volume level. At power-down, the logic first soft-steps the volume down to a mute level, then powers down the circuitry.

## DAC Powerdown

The DAC powerdown flag (D4D3 of control register 05H/page 2) along with D10 of control register 05H/page 2 denotes the powerdown status of the DAC according to Table 2.

**Table 2. DAC Powerdown Status**

| D10, D4, D3 | POWERUP/POWERDOWN STATE OF DAC   |
|-------------|--|
| 0,0,0       | DAC left and right are in stable powerup state.  |
| 0,0,1       | DAC left is in stable powerup state.<br>DAC right is in the process of powering up. The length of this state is determined by PLL and output driver powerup delays controlled by register programming. |
| 0,1,0       | DAC left is in the process of powering up. The length of this state is determined by PLL and output driver powerup delays controlled by register programming.<br>DAC right is in stable powerup state. |
| 0,1,1       | DAC left and right are in the process of powering up. The length of this state is determined by PLL and output driver powerup delays controlled by register programming.                               |
| 1,0,0       | DAC left and right are in the process of powering down. The length of this state is determined by soft-stepping of volume control block.   |
| 1,0,1       | DAC left is in the process of powering down. The length of this state is determined by soft-stepping of volume control block.<br>DAC right is in stable powerdown state.                               |
| 1,1,0       | DAC left is in stable powerdown state.<br>DAC right is in the process of powering down. The length of this state is determined by soft-stepping of volume control block.                               |
| 1,1,1       | DAC left and right are in stable powerdown state.  |

## Analog Outputs

The TSC2101 has the capability to route the DAC output to any of the selected analog outputs. The TSC2101 provides various analog routing capabilities. All analog outputs other than the selected ones are powered down for optimal power consumption.

### ● Headphone Drivers

The TSC2101 features stereo headphone drivers (SPK1 and SPK2) that can deliver 44 mW per channel at 3.3-V supply, into 16-Ω loads. The TSC2101 provides flexibility to connect either of the DAC channels to either of the headphone driver outputs. It also allows mixing of signals from different DAC channels. The headphones can be connected in a single ended configuration using ac-coupling capacitors, or the capacitors can be removed and virtual ground (VGND) powered for a cap-less output connection. Note that the VGND amplifier must be powered up if the cap-less configuration is used.

In the case of an ac-coupled output, the value of the capacitors is typically chosen based on the amount of low-frequency cut that can be tolerated. The capacitor in series with the load impedance forms a high-pass filter with –3 dB cutoff frequency of  $1/(2\pi RC)$  in Hz, where R is the impedance of the headphones. Use of an overly small capacitor reduces low-frequency components in the signal output and lead to low-quality audio. When driving 16-Ω headphones, capacitors of 220-μF (a commonly used value) result in a high-pass filter cutoff frequency of 45 Hz, although reducing these capacitors to 50 μF results in a cutoff frequency of 199 Hz, which is generally considered noticeable when playing music. The cutoff frequency is reduced to half of the above values if 32-Ω headphones are used instead of 16-Ω.

The TSC2101 programmable digital effects block can be used to help reduce the size of capacitors needed by implementing a low frequency boost function to help compensate for the high-pass filter introduced by the ac-coupling capacitors. For example, by using 50-μF capacitors and setting the TSC2101 programmable filter coefficients as shown below, the frequency response can be improved as shown in Figure 21.

Filter coefficients (use the same for both channels):

$$N0 = 32767, N1 = -32346, N2 = 31925, N3 = 32767, N4 = 0, N5 = 0$$

$$D0 = 32738, D1 = -32708, D4 = 0, D5 = 0$$

**Figure 20. Uncompensated Response For 16-Ω Load and 50-μF Decoupling Capacitor**

**Figure 21. Frequency Response For 16-Ω Load and 50-μF Decoupling Capacitor After Gain Compensation Using Above Set of Coefficients For Audio Effects Filter**

Using the capless output configuration eliminates the need for these capacitors and removes the accompanying high-pass filter entirely. However, this configuration does have one drawback – if the RETURN terminal of the headphone jack (which is wired to the TSC2101 VGND pin) is ever connected to a ground that is shorted to the TSC2101 ground pin, then the VGND amplifier enters short-circuit protection, and the audio output does not function properly.

The TSC2101 incorporates a programmable short-circuit detection/protection function. In case of short circuit, all analog outputs are disabled and a *read only* bit D1 of control register 1DH/page 2 is set. In such cases, there are two ways to return to normal operation:

- Hardware or software reset
- Power down all the output drivers, which can be achieved by setting bits D12, D11, D 8, D7, and D6 of control register 05H/page 2 and then wait for driver power down status flags (bits D15–D10 of control register 25H/page 2) to become 1. The wait time is typically less than 50 ms after which, output drivers can be programmed as desired.

For the cap interface, this feature can be disabled by setting bit D0 of control register 20H/page 2. In the case of the cap-less interface, VGND short circuit protection must also be disabled, which can be achieved by setting bit D4 of control register 21H/page 2.

The TSC2101 implements a pop reduction scheme to reduce audible artifacts during powerup and powerdown of headphone drivers. The scheme can be controlled by programming bits D5 and D4 of control register 25H/page 2. By default, the driver pop reduction scheme is enabled and can be disabled by programming bit D5 of control register 25H/page 2 to 1. When this scheme is enabled and the virtual ground connection is not used (VGND amplifier is powered down), the audio output driver slowly charges up any external ac-coupling capacitors to reduce audible artifacts. Bit D4 of control register 25H/page 2 provides control of the charging time for the ac-coupling capacitor as either 0.8 sec or 4 sec. When the virtual ground amplifier is powered up and used, the external ac-coupling capacitor is eliminated, and the powerup time becomes 1 ms. This scheme takes effect whenever any of the headphone drivers are powered up.

- **Speaker Driver**

The TSC2101 has an integrated speaker driver (OUT8P–OUT8N) capable of driving an 8  $\Omega$  differential load. The speaker driver, powered directly from the battery supply (3.5 V to 4.2 V) on the BVDD pin can deliver 400 mW at 3.9 V supply. It allows connecting one or both DAC channel to speaker driver. The TSC2101 also has a short circuit protection feature for the speaker driver which can be enabled by setting bit D5 of control register 21H/page 2.

- **Receiver Driver**

The TSC2101 includes a receiver driver (SPK1–OUT32N), which can drive a 32  $\Omega$  differential load. It is capable of delivering 82 mW into a 32  $\Omega$  load. The TSC2101 does not allow both the receiver driver and headphone drivers to be turned on at the same time. Also, when the receiver driver is being used, the headphone driver load must be disconnected.

## Headset Interface

The TSC2101 supports all standard headset interfaces. It is capable of interfacing with 3-wire stereo headset, 3-wire cellular headset and 4-wire stereo-cellular headsets. It supports both capacitor-coupled (cap) and capacitor-less (capless) interface for headset through software programming.

- **Capless Interface**

Figure 22 shows the connection diagram to the TSC2101 for capless interface. VGND acts as a ground of headset jack. Voltage at VGND is 1.5 V and MICBIAS\_HED voltage is programmed to 3.3 V. With this, the voltage across microphone is configured to be 1.8 V. In order to minimize the effect of routing resistance on VGND inside the device and on the printed circuit board (PCB), SPKFC should be shorted to VGND at the jack. This reduces crosstalk from speaker to microphone because of common ground as VGND.

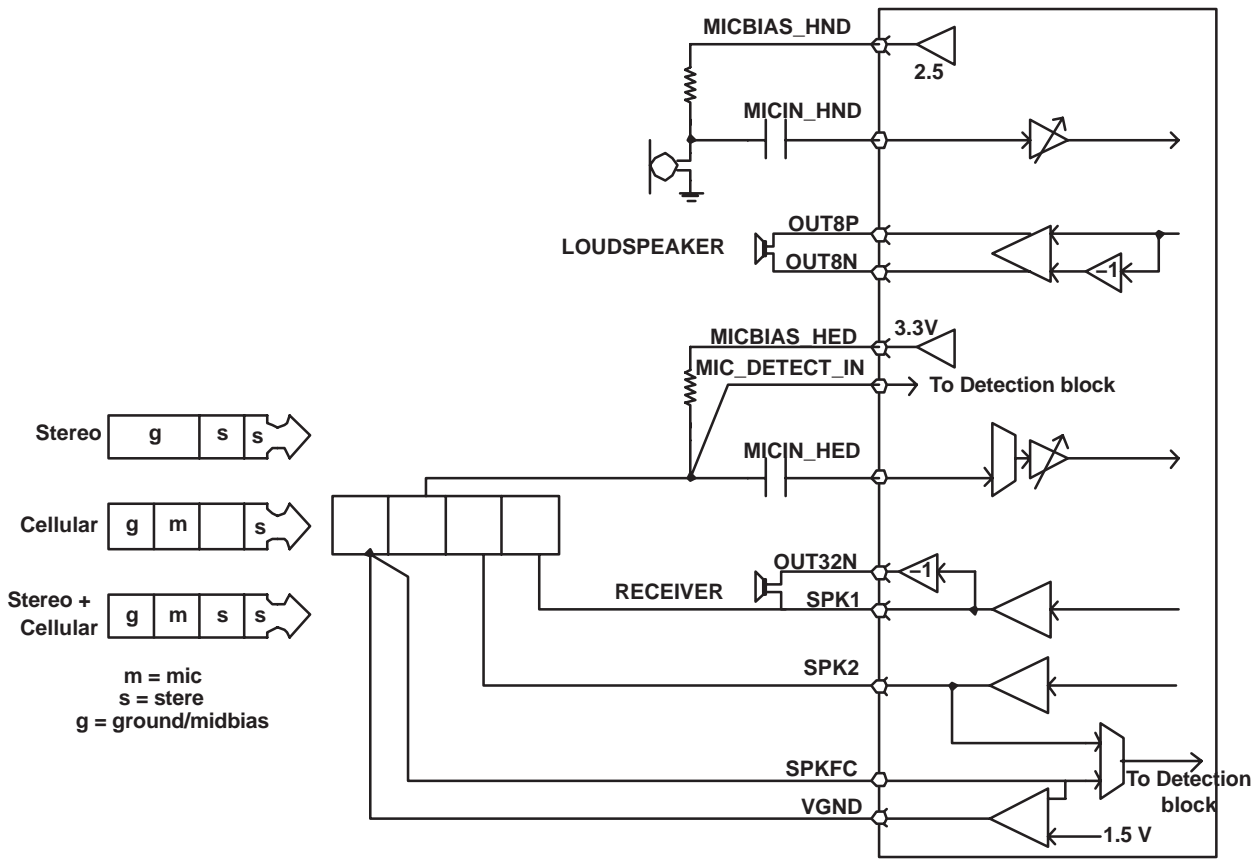

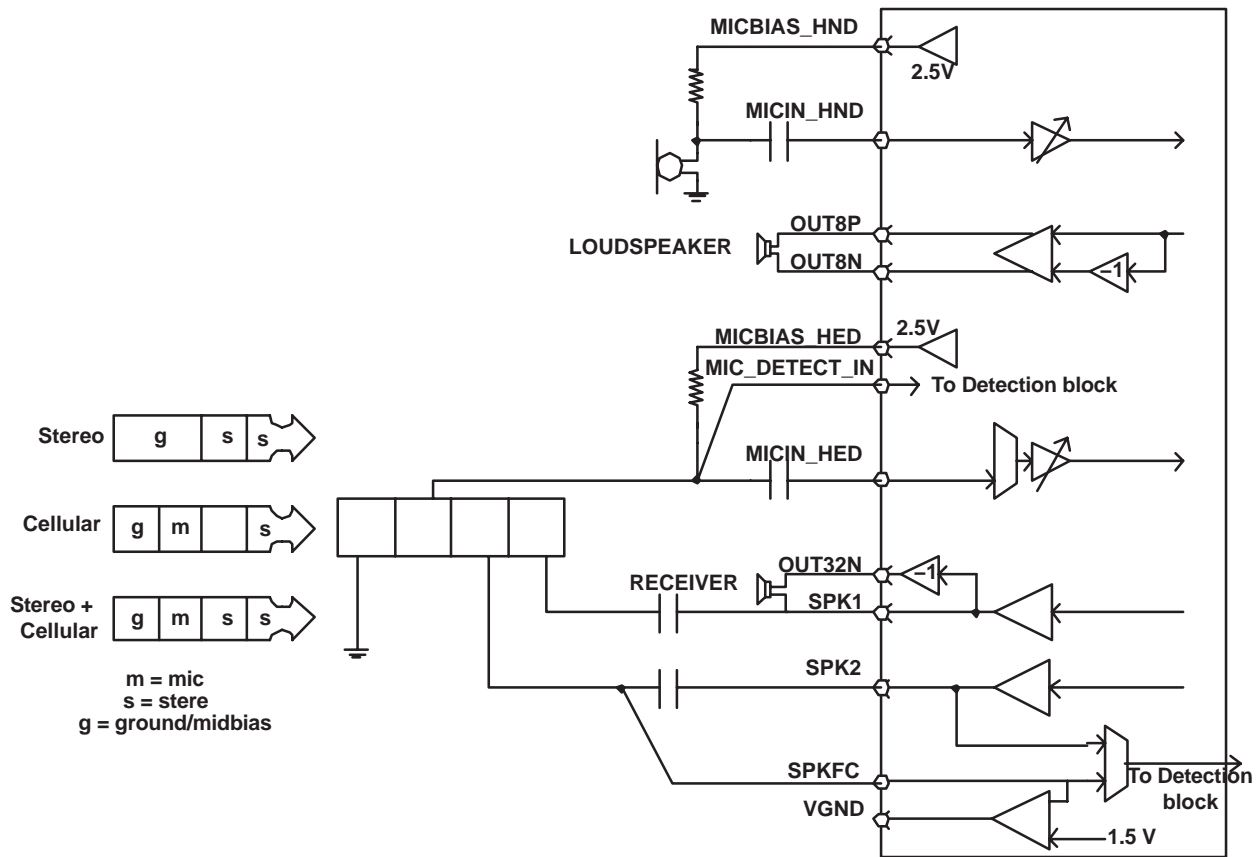

Figure 22. Connection Diagram for Capless Interface

● Cap Interface

Figure 23 shows connection diagram to device for cap interface.

**Figure 23. Connection Diagram for Cap Interface**

● **Auto Detection**

The TSC2101 has built in monitors to automatically detect the insertion and removal of headsets. The detection scheme can differentiate between stereo, cellular and stereo-cellular headsets. Upon detection of headset insertion or removal, the TSC2101 updates read-only bit D12 of control register 22H/Page 2. The TSC2101 can be programmed to send an active high interrupt for insertion and removal of headsets to the host-processor over GPIO1 using bit D3 of control register 22H/Page 2 and GPIO2 using bit D4 of control register 22H/Page 2. The headset detection feature can be enabled by setting bit D15 of control register 22H/Page 2. When headset detection is enabled and headset is not detected, SPK1, VGND and MICBIAS\_HED are turned off irrespective of control register settings. The TSC2101 also has the capability to detect button press on the headset microphone. It consumes less than 50  $\mu$ A while waiting for button press with everything else powered down. Upon button press, the TSC2101 updates read-only bit D11 of control register 22H/Page 2. It can also send an active high interrupt for indicating button press to the processor over GPIO1 using bit D1D0 of control register 22H/Page 2. The TSC2101 provides debounce programmability for headset and button detect. Debounce programmability can be used to reject glitches generated, and hence avoids false detection, while inserting headset or pressing button.

Figure 24 shows terminal connections and jack configuration required for various headsets. Care should be taken to avoid any dc path from MIC\_DETECT\_IN to ground, when a headset is not inserted.

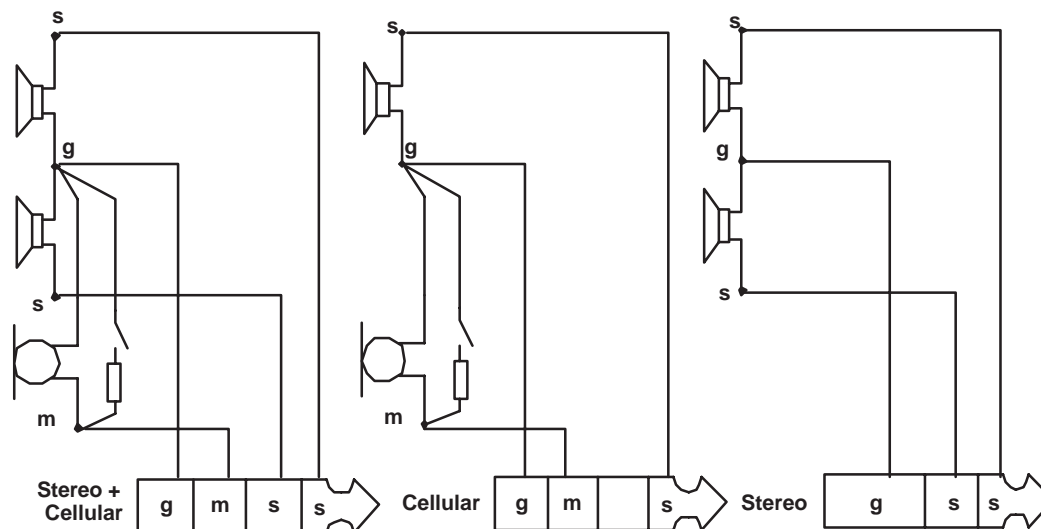

Figure 24. Connection Diagram for Jacks

- **Headset Detection**

- Interrupt polarity: Active high.
- Typical interrupt duration: 1.75 ms.
- Debounce programmability on bits D10 and D9 in control register 22H/Page 2:
  - 00 => 16 ms duration (with 2 ms clock resolution)
  - 01 => 32 ms duration (with 4 ms clock resolution)
  - 10 => 64 ms duration (with 8 ms clock resolution)
  - 11 => 128 ms duration (with 16 ms clock resolution)
- Headset detect flag is available till headset is connected.

- **Button Detection**

- Interrupt polarity: Active high.
- Typical interrupt duration: Button pressed time + clock resolution. Clock resolution depends upon debounce programmability.
- Typical interrupt delay from button: Debounce duration + 0.5ms
- Debounce programmability:
  - 00 => No glitch rejection
  - 01 => 8 ms duration (with 1 ms clock resolution)
  - 10 => 16 ms duration (with 2 ms clock resolution)
  - 11 => 32 ms duration (with 4 ms clock resolution)
- Button detect flag is set when button is pressed. It gets clear when flag read is done after button press removal.

## AUDIO ROUTING

### Audio Interface for Smart-Phone Applications

The TSC2101 supports audio routing features to combine various analog inputs and route them to analog outputs or the ADC for smart-phone applications. In smart-phone applications, the TSC2101 can be used to interface the cell-phone module to microphones and speakers. The TSC2101 allows the input from the cell-phone module to be routed to different speakers through a PGA which supports a range of 12 dB to –34.5 dB in steps of 0.5 dB. The cell-phone input can also be mixed with the microphone input for recording through the ADC. The microphone or DAC audio can be routed to the cell-phone output. The buzzer input from cell-phone can be routed to the speakers through a PGA. The buzzer input supports PGA range of 0 dB to –45 dB in steps of 3 dB. The mixing and PGA are under full software control. The mixing feature can be used even when both ADC and DAC are powered down. Cell-phone PGA, microphone PGA and buzzer PGA includes soft-stepping logic. Soft-stepping logic works on  $F_{sref}$  if DAC is powered up otherwise; it works on internal oscillator clocks.

### Analog Mixer

The analog mixer can be used to route the analog input selected for the ADC through an analog volume control and then mix it with the audio DAC output. The analog mixer feature is available only if the single ended microphone input or the AUX input is selected as the input to the ADC, not when the ADC input is configured in fully-differential mode. This feature is available even if the ADC and DAC are powered down. The analog volume control has a range from +12 dB to –34.5 dB in 0.5 dB steps plus mute and includes soft–stepping logic. The internal oscillator is used for soft–stepping whenever the ADC and DAC are powered down.

### Keyclick

A special circuit has been included for inserting a square–wave signal into the analog output signal path based on register control. This functionality is intended for generating keyclick sounds for user feedback. Register 04H/Page 2 contains bits that control the amplitude, frequency, and duration of the square–wave signal. The frequency of the signal can be varied from 62.5 Hz to 8 kHz and its duration can be programmed from 2 periods to 32 periods. Whenever this register is written, the square wave is generated and coupled into the audio output. The keyclick enable bit D15 of control register 04H/Page 2 is reset after the duration of a keyclick is played out. This capability is available even when the ADC and DAC are powered down.

## OPERATION—TOUCH SCREEN

A resistive touch screen works by applying a voltage across a resistor network and measuring the change in resistance at a given point on the matrix where a screen is touched by an input stylus, pen, or finger. The change in the resistance ratio marks the location on the touch screen.

The TSC2101 supports the resistive 4-wire configurations (see Figure 25). The circuit determines location in two coordinate pair dimensions, although a third dimension can be added for measuring pressure.

### The 4-Wire Touch Screen Coordinate Pair Measurement

A 4-wire touch screen is constructed as shown in Figure 25. It consists of two transparent resistive layers separated by insulating spacers.

**Figure 25. 4-Wire Touch Screen Construction**

The 4-wire touch screen panel works by applying a voltage across the vertical or horizontal resistive network. The ADC converts the voltage measured at the point the panel is touched. A measurement of the Y position of the pointing device is made by connecting the X+ input to an ADC, turning on the Y drivers, and digitizing the voltage seen at the X+ input. The voltage measured is determined by the voltage divider developed at the point of touch. For this measurement, the horizontal panel resistance in the X+ lead does not affect the conversion due to the high input impedance of the ADC.

Voltage is then applied to the other axis, and the ADC converts the voltage representing the X position on the screen. This provides the X and Y coordinates to the associated processor.

Measuring touch pressure (Z) can also be done with the TSC2101. To determine pen or finger touch, the pressure of the *touch* needs to be determined. Generally, it is not necessary to have very high performance for this test; therefore, the 8-bit resolution mode is recommended (however, calculations are shown with the 12-bit resolution mode). There are several different ways of performing this measurement. The TSC2101 supports two methods. The first method requires knowing the X-plate resistance, measurement of the X-Position, and two additional cross panel measurements ( $Z_2$  and  $Z_1$ ) of the touch screen (see Figure 26). Using Equation (1) calculates the touch resistance:

$$R_{\text{TOUCH}} = R_{\text{X-plate}} \times \frac{\text{X-position}}{4096} \left( \frac{Z_2}{Z_1} - 1 \right) \quad (1)$$

The second method requires knowing both the X-plate and Y-plate resistance, measurement of X-Position and Y-Position, and  $Z_1$ . Using Equation (2) also calculates the touch resistance:

$$R_{\text{TOUCH}} = \frac{R_{\text{X-plate}} \times \text{X-position}}{4096} \left( \frac{4096}{Z_1} - 1 \right) - R_{\text{Y-plate}} \times \left( 1 - \frac{\text{Y-position}}{4096} \right) \quad (2)$$

**Figure 26. Pressure Measurement**

When the touch panel is pressed or touched, and the drivers to the panel are turned on, the voltage across the touch panel often overshoots and then slowly settles (decays) down to a stable DC value. This is due to mechanical bouncing which is caused by vibration of the top layer sheet of the touch panel when the panel is pressed. This settling time must be accounted for, or else the converted value will be in error. Therefore, a delay must be introduced between the time the driver for a particular measurement is turned on, and the time measurement is made.

In some applications, external capacitors may be required across the touch screen for filtering noise picked up by the touch screen, i.e., noise generated by the LCD panel or back-light circuitry. The value of these capacitors provides a low-pass filter to reduce the noise, but causes an additional settling time requirement when the panel is touched.

Several solutions to this problem are available in the TSC2101. A programmable delay time is available which sets the delay between turning the drivers on and making a conversion. This is referred to as the panel voltage stabilization time, and is used in some of the modes available in the TSC2101. In other modes, the TSC2101 can be commanded to turn on the drivers only without performing a conversion. Time can then be allowed before the command is issued to perform a conversion.

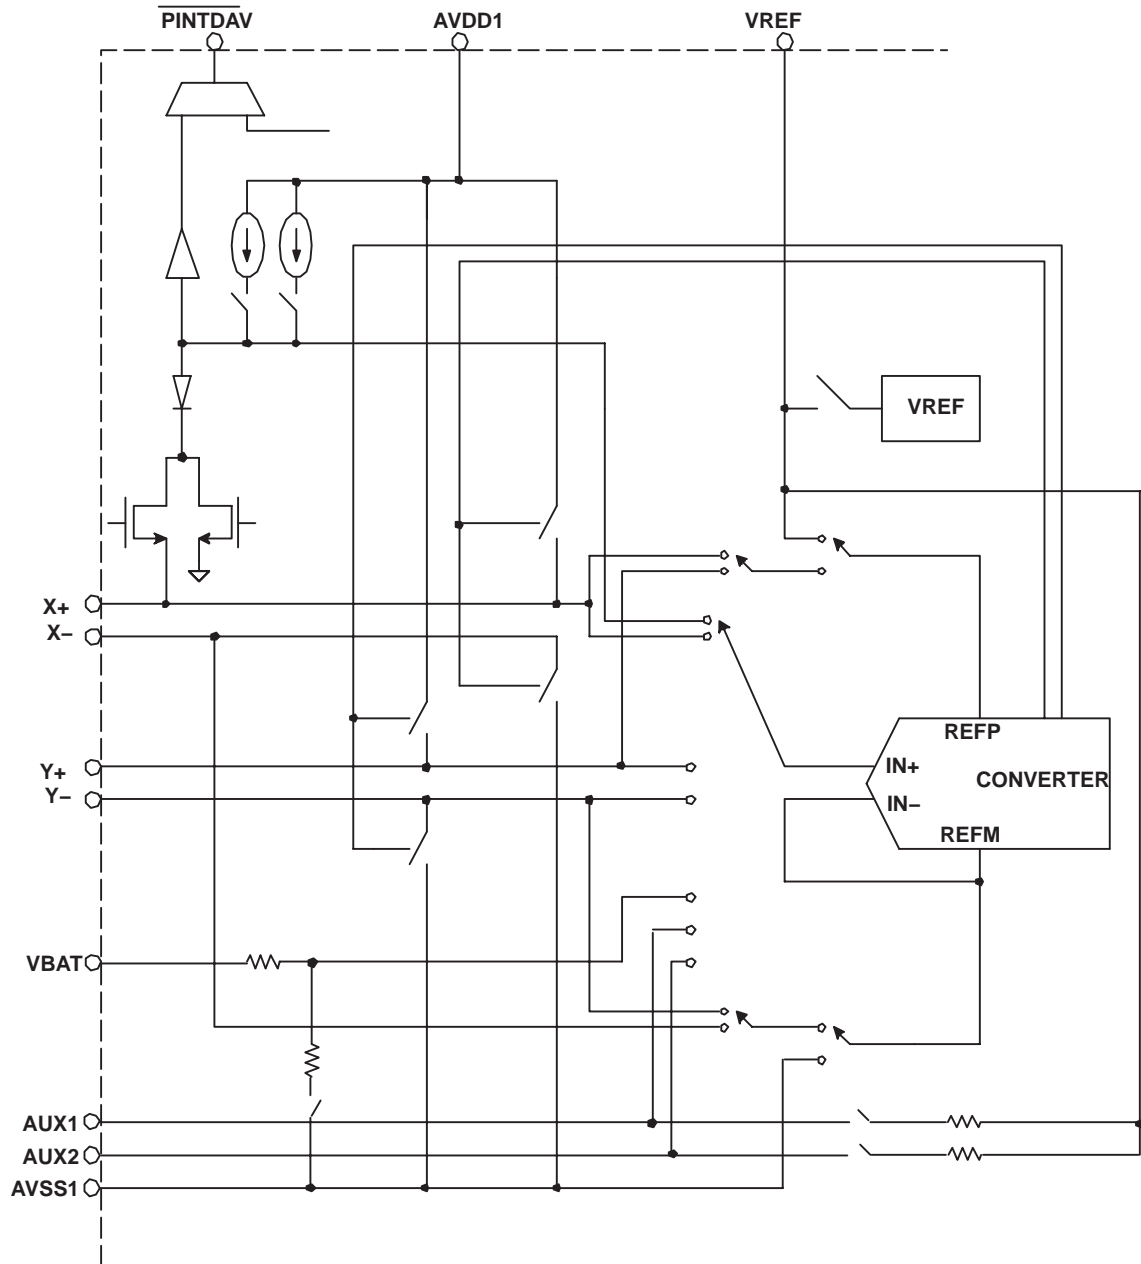

The TSC2101 touch screen interface can measure position (X, Y) and pressure (Z). Determination of these coordinates is possible under three different modes of the ADC: (1) conversion controlled by the TSC2101, initiated by detection of a touch; (2) conversion controlled by the TSC2101, initiated by the host responding to the  $\overline{\text{PINTDAV}}$  signal; or (3) conversion completely controlled by the host processor.

### Touch Screen ADC Converter

The analog inputs of the TSC2101 are shown in Figure 27. The analog inputs (X, Y, and Z touch panel coordinates, battery voltage monitors, chip temperature and auxiliary input) are provided via a multiplexer to the successive approximation register (SAR) analog-to-digital (A/D) converter. The ADC architecture is based on capacitive redistribution architecture, which inherently includes a sample/hold function.

A unique configuration of low on-resistance switches allows an unselected ADC input channel to provide power and an accompanying pin to provide ground for driving the touch panel. By maintaining a differential input to the converter and a differential reference input architecture, it is possible to negate errors caused by the driver switch on-resistances.

The ADC is controlled by an ADC control register. Several modes of operation are possible, depending upon the bits set in the control register. Channel selection, scan operation, averaging, resolution, and conversion rate may all be programmed through this register. These modes are outlined in the sections below for each type of analog input. The results of conversions made are stored in the appropriate result register.

**Figure 27. Simplified Diagram of the Analog Input Section**

**Data Format**

The TSC2101 output data is in unsigned Binary format and can be read from registers over the SPI interface.

**Reference**

The TSC2101 has an internal voltage reference that can be set to 1.25 V or 2.5 V, through the reference control register.

The internal reference voltage should only be used in the single-ended mode for battery monitoring, temperature measurement, and for utilizing the auxiliary inputs. Optimal touch-screen performance is achieved when using a ratiometric conversion, thus all touch-screen measurements are done automatically in the ratiometric mode.

An external reference can also be applied to the VREF pin, and the internal reference can be turned off.

### Variable Resolution

The TSC2101 provides three different resolutions for the ADC: 8, 10 or 12 bits. Lower resolutions are often practical for measurements such as touch pressure. Performing the conversions at lower resolution reduce the amount of time it takes for the ADC to complete its conversion process, which lowers power consumption.

### Conversion Clock and Conversion Time

The TSC2101 contains an internal 8 MHz clock, which is used to drive the state machines inside the device that perform the many functions of the part. This clock is divided down to provide a clock to run the ADC. The division ratio for this clock is set in the ADC control register. The ability to change the conversion clock rate allows the user to choose the optimal value for resolution, speed, and power. If the 8 MHz clock is used directly, the ADC is limited to 8-bit resolution; using higher resolutions at this speed does not result in accurate conversions. Using a 4 MHz conversion clock is suitable for 10-bit resolution; 12-bit resolution requires that the conversion clock run at 1 or 2 MHz.

Regardless of the conversion clock speed, the internal clock runs nominally at 8 MHz. The conversion time of the TSC2101 is dependent upon several functions (see the section *Touch Screen Conversion Initiated at Touch Detect* in this data sheet). While the conversion clock speed plays an important role in the time it takes for a conversion to complete, a certain number of internal clock cycles are needed for proper sampling of the signal. Moreover, additional times, such as the panel voltage stabilization time, can add significantly to the time it takes to perform a conversion. Conversion time can vary depending upon the mode in which the TSC2101 is used. Throughout this data sheet, internal and conversion clock cycles are used to describe the times that many functions take to execute. Considering the total system design, these times must be taken into account by the user.

When both the audio ADC and DAC are powered down, the touch screen ADC uses an internal oscillator for conversions. However, to save power whenever audio ADC or DAC are powered up, the internal oscillator is powered down and MCLK and BCLK are used to clock the touch screen ADC.

The TSC2101 uses the programmed value of bit D13 in control register 06H/page 2 and the PLL programmability to derive a clock from MCLK. The various combinations are listed in Table 3.

**Table 3. Conversion Clock Frequency**

|              | D13=0 (in control register 06H/page 2)         | D13=1 (in control register 06H/page 2)         |
|--------------|--|--|
| PLL enabled  | $\frac{MCLK \times K \times 13}{P \times 160}$ | $\frac{MCLK \times K \times 17}{P \times 192}$ |
| PLL disabled | $\frac{MCLK \times 13}{Q \times 10}$           | $\frac{MCLK \times 17}{Q \times 12}$           |

### Touch Detect/Data Available

The pen interrupt/data available ( $\overline{\text{PINTDAV}}$ ) output function is detailed in Figure 28. While in the power-down mode, the Y– driver is ON and connected to AVSS2 and the X+ pin is connected through an on-chip pull-up resistor to AVDD2. In this mode, the X+ pin is also connected to a digital buffer and mux to drive the  $\overline{\text{PINTDAV}}$  output. When the panel is touched, the X+ input is pulled to ground through the touch screen and pen-interrupt signal goes LOW due to the current path through the panel to AVSS2, initiating an interrupt to the processor. During the measurement cycles for X– and Y– position, the X+ input is disconnected from the pen-interrupt circuit to prevent any leakage current from the pull-up resistor flowing through the touch screen, and thus causing conversion errors.

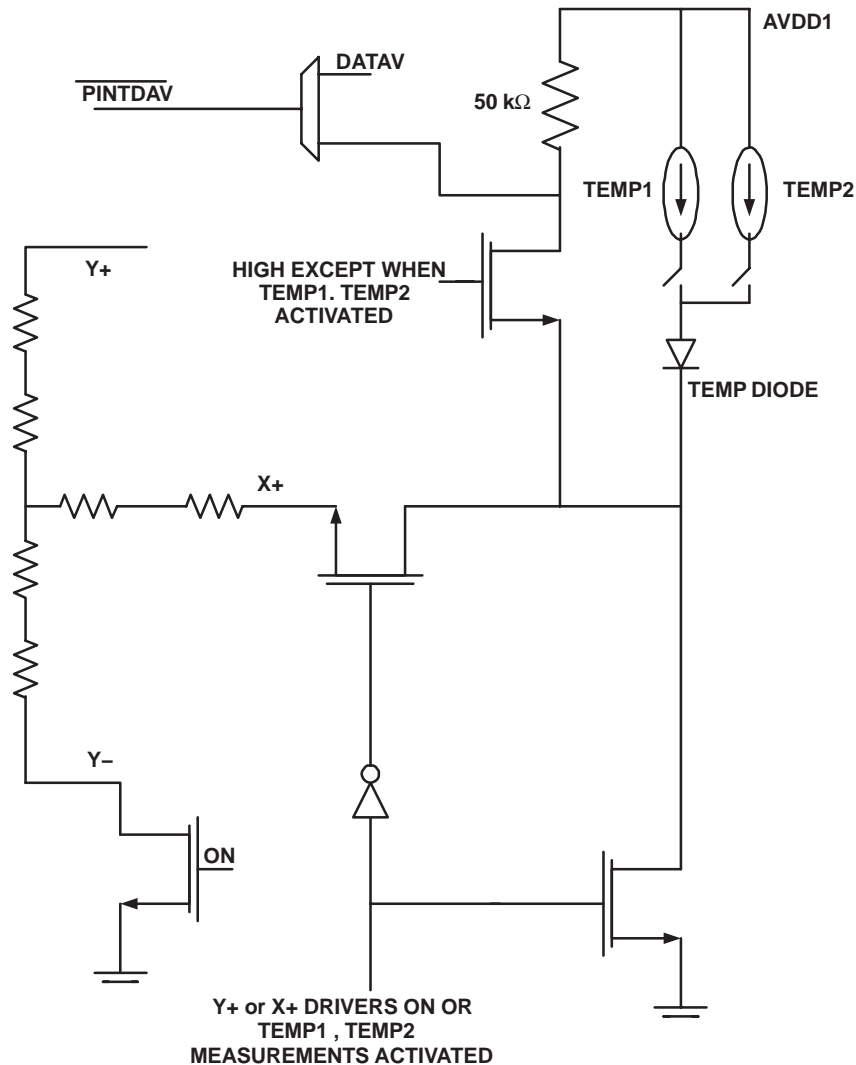

Figure 28.  $\overline{\text{PINTDAV}}$  Functional Block Diagram

In modes where the TSC2101 needs to detect if the screen is still touched (for example, when doing a  $\overline{\text{PINTDAV}}$  initiated X, Y, and Z conversion), the TSC2101 must reset the drivers so that the 50 KΩ resistor is connected. Because of the high value of this pull-up resistor, any capacitance on the touch screen inputs causes a long delay time, and may prevent the detection from occurring correctly. To prevent this, the TSC2101 has a circuit that allows any screen capacitance to be *precharged*, so that the pull-up resistor does not have to be the only source for the charging current. The time allowed for this precharge, as well as the time needed to sense if the screen is still touched, can be set in the configuration control register D5–D0 of register 05H/Page 1.

This does point out, however, the need to use the minimum capacitor values possible on the touch screen inputs. These capacitors may be needed to reduce noise, but too large a value will increase the needed precharge and sense times, as well as panel voltage stabilization time.

The function of  $\overline{\text{PINTDAV}}$  output is programmable and controlled by writing to the bits D15–D14 of control register 01H/Page 1 as described in the Table 4.

**Table 4. Programmable  $\overline{\text{PINTDAV}}$  Functionality**

| D15–D14  | $\overline{\text{PINTDAV}}$ FUNCTION  |
|----------|---|
| 00       | Acts as PEN interrupt (active low) only. When PEN touch is detected, $\overline{\text{PINTDAV}}$ goes low.  |
| 01       | Acts as data available (active low) only. The $\overline{\text{PINTDAV}}$ goes low as soon as one set of ADC conversions are completed for data of X,Y, XYZ, battery input, or auxiliary input selected by D13–D10 in control register 00H/Page 1. The resulting ADC output is stored in the appropriate registers. The $\overline{\text{PINTDAV}}$ remains low and goes high only after this complete set of registers selected by D13–D10 in control register 00H/Page 1 is read out. |
| 10<br>11 | Acts as both PEN interrupt and data available. When PEN touch is detected, $\overline{\text{PINTDAV}}$ goes low and remains low. The $\overline{\text{PINTDAV}}$ goes high only after one set of A/D conversions is completed for data of X,Y, XYZ, battery input, or auxiliary input selected by D13–D10 in control register 00H/Page 1.   |

NOTE: See the section, Conversion Time Calculations for the TSC2101 in this data sheet for the timing diagrams.

Pen-touch detect circuit is disabled during hardware power down.

### Touch Screen Measurements

The touch screen ADC can be either controlled by the host processor or can be self-controlled to offload processing from the host processor. Bit D12 of control register 01H/Page 1 sets the control mode of the TSC2101 touch screen ADC.

### Conversion Controlled by the TSC2101 Initiated at Touch Detect

In this mode, the TSC2101 detects when the touch panel is touched and causes the  $\overline{\text{PINTDAV}}$  line to go low. At the same time, the TSC2101 starts up its internal clock. Assuming the part was configured to convert XY coordinates, it then turns on the Y drivers, and after a programmed panel voltage stabilization time, powers up the ADC and converts the Y coordinate. If averaging is selected, several conversions may take place; when data averaging is complete, the Y coordinate result is stored in the Y register.

If the screen is still touched at this time, the X drivers are enabled, and the process repeats, but measuring instead the X coordinate, storing the result in the X register.

If only X and Y coordinates are to be measured, then the conversion process is complete. The time it takes to complete this process depends upon the selected resolution, internal conversion clock rate, averaging selected, panel voltage stabilization time, and precharge and sense times.

If the pressure of the touch is also to be measured, the process continues in the same way, measuring the Z1 and Z2 values, and placing them in the Z1 and Z2 registers. As before, this process time depends upon the settings described above.

See the section *Conversion Time Calculation for the TSC2101* in this data sheet for timing diagrams and conversion time calculations.

### Conversion Controlled by the TSC2101 Initiated by the Host

In this mode, the TSC2101 detects when the touch panel is touched and causes the  $\overline{\text{PINTDAV}}$  line to go low. The host recognizes the interrupt request, and then writes to the ADC control register (D13–D10 of control register 00H/Page 1) to select one of the touch screen scan functions. The host can either choose to initiate one of the scan functions, in which case the TSC2101 controls the driver turn-on and wait times (e.g. upon receiving the interrupt the host can initiate the continuous scan function X–Y–Z1–Z2 after which the TSC2101 controls the rest of conversion). The host can also choose to control each aspect of conversion by controlling the driver turn-on and start of conversions. For example, upon receiving the interrupt request, the host turns on the X drivers. After waiting for the settling time, the host then addresses the TSC2101 again, this time requesting an X coordinate conversion, and so on.

The main difference between this mode and the previous mode is that the host, not the TSC2101, controls the touch screen scan functions.

See the section *Conversion Time Calculation for the TSC2101* in this data sheet for timing diagrams and conversion time calculations.

## Temperature Measurement

In some applications, such as battery charging, a measurement of ambient temperature is required. The temperature measurement technique used in the TSC2101 relies on the characteristics of a semiconductor junction operating at a fixed current level. The forward diode voltage ( $V_{BE}$ ) has a well-defined characteristic versus temperature. The ambient temperature can be predicted in applications by knowing the 25°C value of the  $V_{BE}$  voltage and then monitoring the variation of that voltage as the temperature changes.

The TSC2101 offers two modes of temperature measurement. The first mode requires a single reading to predict the ambient temperature. A diode, as shown in Figure 29, is used during this measurement cycle. This voltage is typically 600 mV at +25°C with a 20- $\mu$ A current through it. The absolute value of this diode voltage can vary a few millivolts. The temperature coefficient of this voltage is typically 2 mV/°C. During the final test of the end product, the diode voltage at a known room temperature should be stored in nonvolatile memory. Further calibration can be done to calculate the precise temperature coefficient of the particular. This method has a temperature resolution of approximately 0.3°C/LSB and accuracy of approximately  $\pm 2^\circ\text{C}$  with two-temperature calibration. Figure 30 and Figure 31 shows typical plots with single and two-temperature calibration respectively.

**Figure 29. Functional Block Diagram of Temperature Measurement Mode**

**Figure 30. Typical Plot of Single Measurement Method After Calibrating for Offset at Room Temperature**

**Figure 31. Typical Plot of Single Measurement Method After Calibrating for Offset and Gain At Two Temperatures**

The second mode uses a two-measurement (differential) method. This mode requires a second conversion with a current 82 times larger. The voltage difference between the first (TEMP1) and second (TEMP2) conversion, using 82 times the bias current, is represented by:

$$\frac{kT}{q} \times \ln(N)$$

where:

N is the current ratio = 82

k = Boltzmann's constant ( $1.38054 \cdot 10^{-23}$  electrons volts/degrees Kelvin)

q = the electron charge ( $1.602189 \cdot 10^{-19}$  °C)

T = the temperature in degrees Kelvin

The equation for the relation between differential code and temperature may vary slightly from device to device and can be calibrated at final system test by the user. This method provides resolution of approximately 1.5°C/LSB and accuracy of approximately  $\pm 4^\circ\text{C}$  after calibrating at room temperature.

**Figure 32. Typical Plot of Differential Measurement Method After Calibrating for Offset at Room Temperature**

The TSC2101 supports programmable auto-temperature measurement mode, which can be enabled using control register 0CH/page 1. In this mode, the TSC2101 can auto-start the temperature measurement after a programmable interval. The user can program minimum and maximum threshold values through a register. If the measurement goes outside the threshold range, the TSC2101 sets a flag in the read only control register 0CH/page 1, which gets cleared after the flag is read. The TSC2101 can also be configured to send an active high interrupt over GPIO1 by setting D9 in control register 0CH/page 1. The duration of the interrupt is approximately 2 ms.

Temperature measurement can only be done in host controlled mode.

### Battery Measurement

An added feature of the TSC2101 is the ability to monitor the battery voltage on the other side of a voltage regulator (dc/dc converter), as shown in Figure 33. The battery voltage can vary from 0.5 V to 6 V while maintaining the analog supply voltage to the TSC2101 at 3.0 V to 3.6 V. The input voltage (VBAT) is divided down by a factor of 5 so that a 6.0 V battery voltage is represented as 1.2 V to the ADC. In order to minimize the power consumption, the divider is only on during the sampling of the battery input.

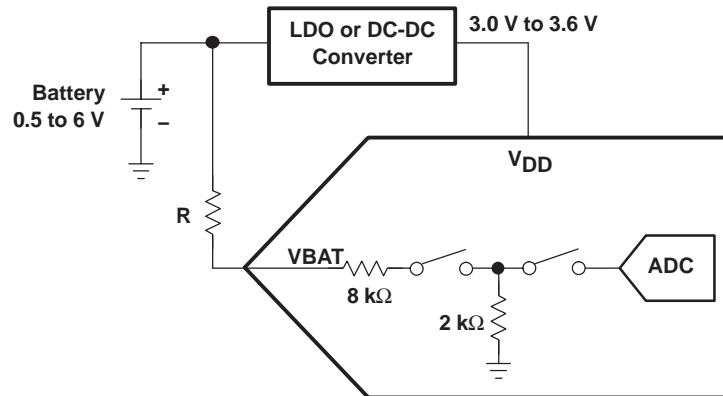

If the battery conversion results in A/D output code of  $B$ , the voltage at the battery pin can be calculated as:

$$V_{\text{BAT}} = \frac{B}{2^N} \times 5 \times V_{\text{REF}}$$

Where:

$N$  is the programmed resolution of A/D

$V_{\text{REF}}$  is the programmed value of internal reference or the applied external reference.

**Figure 33. Battery Measurement Functional Block Diagram**

Battery measurement can only be done in host-controlled mode.

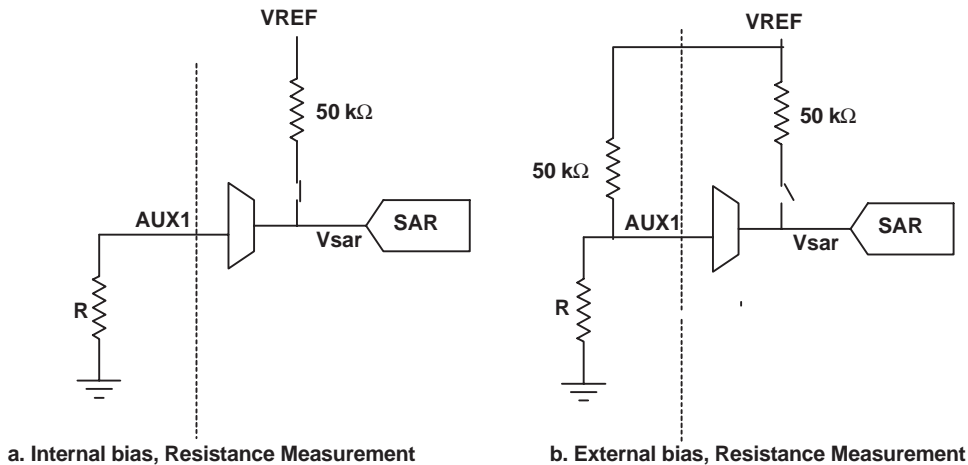

See the section *Conversion Time Calculation for the TSC2101* and subsection *Non Touch Measurement Operation* in this data sheet for timing diagrams and conversion time calculations.

For increased protection and robustness, TI recommends a minimum 100-Ω resistor be added in series between the system battery and the VBAT pin. The 100-Ω resistor will cause an approximately 1% gain change in the battery voltage measurement, which can easily be corrected in software when the battery conversion data is read by the operating system.

**Auxiliary Measurement**

The auxiliary voltage inputs (AUX1 and AUX2) can be measured in much the same way as the battery inputs except the difference that input voltage is not divided. Applications might include external temperature sensing, ambient light monitoring for controlling the backlight, or sensing the current drawn from the battery. The auxiliary input can also be monitored continuously in scan mode.

The TSC2101 provides feature to measure resistance using auxiliary inputs. It has two modes of operation: (1) External bias resistance measurement (2) Internal bias resistance measurement. Internal bias resistance measurement mode does not need an external bias resistance of 50 kΩ, but provides less accuracy because of on chip resistance variation, which is typically ±20%. Figure 34 shows connection diagram for resistance measurement mode on AUX1.

**Figure 34. Connection Diagram for Resistance Measurement**

Resistance can be calculated using following formula:

$$R = 50 \text{ K}\Omega \times \frac{V_{sar}}{V_{REF} - V_{sar}}$$

Where:

VREF is the SAR ADC reference

Vsar is input to the SAR ADC

The TSC2101 supports programmable auto–auxiliary measurement mode, which can be enabled using control register 0CH/page 1. In this mode, the TSC2101 can auto start the auxiliary measurement after a programmable interval. The user can program minimum and maximum threshold values through a register. If the measurement goes outside the threshold range, the TSC2101 sets a flag in the read only control register 0CH/page 1, which gets cleared after the flag is read. The TSC2101 can also be configured to send an active high interrupt over GPIO1 by setting D9 of control register 0CH/page 1. The duration of the interrupt is approximately 2 ms.

Auxiliary measurement can only be done in host–controlled mode.

See the section *Conversion Time Calculation for the TSC2101* and subsection *Non Touch Measurement Operation* in this data sheet for timing diagram and conversion time calculation

### Port Scan

If making measurements of VBAT, AUX1, and AUX2 is desired on a periodic basis, the Port Scan mode can be used. This mode causes the TSC2101 to sample and convert battery input and both auxiliary inputs. At the end of this cycle, the battery and auxiliary result registers contain the updated values. Thus, with one write to the TSC2101, the host can cause three different measurements to be made.

Port Scan can only be done in host-controlled mode. See the section *Issues* at the end of this data sheet for details of a known issue with this mode.

See the section *Conversion Time Calculation for the TSC2101* and subsection *Port Scan Operation* in this data sheet for timing diagrams and conversion time calculations.

### Buffer Mode

The TSC2101 supports a programmable buffer mode, which is applicable for both touch screen related conversion (X, Y, Z1, Z2) and nontouch screen related conversion (BAT, AUX1, AUX2, TEMP1, TEMP2). Buffer mode is implemented using a circular FIFO with a depth of 64. The number of interrupts required to be serviced by a host processor can be reduced significantly buffer mode. Buffer mode can be enabled using control register 02H/page1.

**Figure 35. Circular Buffer**

Converted data is automatically written into the FIFO. To control the writing, reading and interrupt process, a write pointer (WRPTR), a read pointer (RDPTR) and a trigger pointer (TGPTR) are used. The read pointer always shows the location, which will be read next. The write pointer indicates the location, in which the next converted data is going to be written. The trigger pointer indicates the location at which an interrupt will be generated if the write pointer reaches that location. Trigger level is the number of the data points needed to be present in the FIFO before generating an interrupt. For e.g., X–Y continuous scan mode with trigger level set to 8, the TSC2101 generates interrupt after writing (X1, Y1), (X2, Y2), (X3, Y3), (X4, Y4) i.e. 4 data-pairs or 8 data. Figure 35 shows the case when trigger level is programmed as 32. On resetting buffer mode, RDPTR moves to location 1, WRPTR moves to location 1, and TGPTR moves to location equal to programmed trigger level.

The user can select the input or input sequence, which needs to be converted, from the ADCSM bits of control register 00H/page 1. The converted values are written in a predefined sequence to the circular buffer. The user has flexibility to program a specific trigger level in order to choose the configuration which best fits the application. When the number of converted data, written in FIFO, becomes equal to the programmed trigger level then the device generates an interrupt signal on /PINTDAV pin. In buffer mode, the user should program this pin as Data Available (DATA\_AVA). In buffer mode, touch screen related conversions (X, Y, Z1, Z2) are allowed only in self-controlled mode and nontouch screen related conversions (BAT, AUX1, AUX2, TEMP1, TEMP2) are allowed only in host-controlled mode.

Buffer mode can be used in single-shot conversion or continuous conversion mode.

In single shot conversion mode, once the number of data written reaches programmed trigger level, the TSC2101 generates an interrupt and waits for the user to start reading. As soon as the user starts reading the first data from the last converted set, the TSC2101 clears the interrupt and starts a new set of conversions and the trigger pointer is incremented by the programmed trigger level. An interrupt is generated again when the trigger condition is satisfied.

In continuous conversion mode, once number of data written reaches the programmed trigger level, the TSC2101 generates an interrupt. It immediately starts a new set of conversions and the trigger pointer is incremented by the programmed trigger level. An interrupt gets cleared either by writing the next converted data into the FIFO or by starting to read from the FIFO.

See the section *Conversion Time Calculation for the TSC2101* and subsection *Buffer Mode Operation* in this data sheet for timing diagrams and conversion time calculations.

Depending upon how the user is reading data, the FIFO can become empty or full. If the user is trying to read data even if the FIFO is empty, then RDPTR keeps pointing to same location. If the FIFO gets full then the next location is overwritten with newly converted data and the read pointer is incremented by one.

While reading the FIFO, the TSC2101 provides FIFO empty and full status flags along with the data. The user can also read a status flag from control register 02H/page 1.

## DIGITAL INTERFACE

### RESET

The device requires reset after power up. This requires a low-to-high transition on the RESET pin after power up for correct operation. Reset initializes all the internal registers, counters and logic.

### Hardware Power-Down

Hardware power-down powers down all the internal circuitry to save power. All the register contents are maintained. Putting the TSC2101 into hardware power-down circuit also disables the pen-touch detect circuit.

### General Purpose I/O

The TSC2101 has two general purpose I/O (GPIO1 and GPIO2), which can be programmed either as inputs or outputs. As outputs they can be programmed to control external logic through the TSC2101 registers or send interrupts to the host processor on events like button detect, headset insertion, headset removal, Auxiliary/temperature outside threshold range etc. As inputs they can be used by the host-processor to monitor logic states of signals on the system through the TSC2101 registers.

## SPI Digital Interface

All TSC2101 control registers are programmed through a standard SPI bus. The SPI allows full-duplex, synchronous, serial communication between a host processor (the master) and peripheral devices (slaves). The SPI master generates the synchronizing clock and initiates transmissions. The SPI slave devices depend on a master to start and synchronize transmissions.

A transmission begins when initiated by a master SPI. The byte from the master SPI begins shifting in on the slave MOSI pin under the control of the master serial clock. As the byte shifts in on the MOSI pin, a byte shifts out on the MISO pin to the master shift register.

The idle state of the serial clock for the TSC2101 is low, which corresponds to a clock polarity setting of 0 (typical microprocessor SPI control bit CPOL = 0). The TSC2101 interface is designed so that with a clock phase bit setting of 1 (typical microprocessor SPI control bit CPHA = 1), the master begins driving its MOSI pin and the slave begins driving its MISO pin on the first serial clock edge. The  $\overline{SS}$  pin can remain low between transmissions; however, the TSC2101 only interprets command words which are transmitted after the falling edge of  $\overline{SS}$ .

## TSC2101 COMMUNICATION PROTOCOL

### Register Programming

The TSC2101 is entirely controlled by registers. Reading and writing these registers is controlled by an SPI master and accomplished by the use of a 16-bit command, which is sent prior to the data for that register. The command is constructed as shown in Figure 36.

The command word begins with an R/W bit, which specifies the direction of data flow on the SPI serial bus. The following 4 bits specify the page of memory this command is directed to, as shown in Table 5. The next six bits specify the register address on that page of memory to which the data is directed. The last five bits are reserved for future use and should be written only with zeros.

**Table 5. Page Addressing**

| PG3 | PG2 | PG1 | PG0 | PAGE ADDRESSED |
|-----|-----|-----|-----|----------------|
| 0   | 0   | 0   | 0   | 0              |
| 0   | 0   | 0   | 1   | 1              |
| 0   | 0   | 1   | 0   | 2              |
| 0   | 0   | 1   | 1   | 3              |
| 0   | 1   | 0   | 0   | Reserved       |
| 0   | 1   | 0   | 1   | Reserved       |
| 0   | 1   | 1   | 0   | Reserved       |
| 0   | 1   | 1   | 1   | Reserved       |
| 1   | 0   | 0   | 0   | Reserved       |
| 1   | 0   | 0   | 1   | Reserved       |
| 1   | 0   | 1   | 0   | Reserved       |
| 1   | 0   | 1   | 1   | Reserved       |
| 1   | 1   | 0   | 0   | Reserved       |
| 1   | 1   | 0   | 1   | Reserved       |
| 1   | 1   | 1   | 0   | Reserved       |
| 1   | 1   | 1   | 1   | Reserved       |

To read all the first page of memory, for example, the host processor must send the TSC2101 the command 0x8000 – this specifies a read operation beginning at page 0, address 0. The processor can then start clocking data out of the TSC2101. The TSC2101 automatically increments its address pointer to the end of the page; if the host processor continues clocking data out past the end of a page, the TSC2101 sends back the value 0xFFFF.

Likewise, writing to page 1 of memory would consist of the processor writing the command 0x0800, which specifies a write operation, with PG0 set to 1, and all the ADDR bits set to 0. This results in the address pointer pointing at the first location in memory on page 1. See the section on the TSC2101 memory map for details of register locations.

TSC2101 Memory Map

The TSC2101 has several 16-bit registers which allow control of the device as well as providing a location for results from the TSC2101 to be stored until read by the host microprocessor. These registers are separated into four pages of memory in the TSC2101: a data page (page 0), control pages (page 1 and page 2) and a buffer data page (page 3). The memory map is shown in Table 6.

### TSC2101 Control Registers

This section describes each of the registers shown in the memory map of Table 6. The registers are grouped according to the function they control. Note that in the TSC2101, bits in control registers may refer to slightly different functions depending upon if you are reading the register or writing to it.

### TSC2101 Data Registers (Page 0)

The data registers of the TSC2101 hold data results from conversion of touch screen ADC. All of these registers default to 0000H upon reset. These registers are *read only*.

**X, Y, Z1, Z2, BAT, AUX1, AUX2, TEMP1 and TEMP2 Registers**

The results of all ADC conversions are placed in the appropriate data register. The data format of the result word, R, of these registers is right-justified, as follows:

|               |        |        |        |            |        |       |       |       |       |       |       |       |       |       |              |

**TSC2101 Buffer Data Registers (Page 3)**

The buffer data registers of the TSC2101 hold data results from the SAR ADC conversions in buffer mode. Upon reset, bit D15 is set to 0, bit D14 is set to 1 and the remaining bits are don't–care. These registers are *read only*.

If buffer mode is enabled, then the results of all ADC conversions are placed in the buffer data register. The data format of the result word (R) of these registers is right-justified which is as follows:

|         |     |     |     |         |     |    |    |    |    |    |    |    |    |    |        |

## LAYOUT

The following layout suggestions should provide optimum performance from the TSC2101. However, many portable applications have conflicting requirements concerning power, cost, size, and weight. In general, most portable devices have fairly *clean* power and grounds because most of the internal components are very low power. This situation would mean less bypassing for the converter's power and less concern regarding grounding. Still, each situation is unique and the following suggestions should be reviewed carefully.

For optimum performance, care should be taken with the physical layout of the TSC2101 circuitry. The basic SAR architecture is sensitive to glitches or sudden changes on the power supply, reference, ground connections, and digital inputs that occur just prior to latching the output of the analog comparator. Therefore, during any single conversion for an *n-bit* SAR converter, there are *n windows* in which large external transient voltages can easily affect the conversion result. Such glitches might originate from switching power supplies, nearby digital logic, and high power devices. The degree of error in the digital output depends on the reference voltage, layout, and the exact timing of the external event. The error can change if the external event changes in time with respect to the timing of the critical *n windows*.

With this in mind, power to the TSC2101 should be clean and well bypassed. A 0.1  $\mu\text{F}$  ceramic bypass capacitor should be placed as close to the device as possible. A 1  $\mu\text{F}$  to 10  $\mu\text{F}$  capacitor may also be needed if the impedance of the connection between the TSC2101 supply pins and system power supply is high.

A bypass capacitor on the VREF pin is generally not needed because the reference is buffered by an internal op amp, although it can be useful to reduce reference noise level. If an external reference voltage originates from an op amp, make sure that it can drive any bypass capacitor that is used without oscillation.

The TSC2101 architecture offers no inherent rejection of noise or voltage variation in regards to using an external reference input. This is of particular concern when the reference input is tied to the power supply. Any noise and ripple from the supply appears directly in the digital results. While high frequency noise can be filtered out, voltage variation due to line frequency (50 Hz or 60 Hz) can be difficult to remove.

The ground pins should be connected to a clean ground point. In many cases, this is the *analog* ground. Avoid connections, which are too near the grounding point of a microcontroller or digital signal processor. If needed, run a ground trace directly from the converter to the power supply entry or battery connection point. The ideal layout includes an analog ground plane dedicated to the converter and associated analog circuitry.

In the specific case of use with a resistive touch screen, care should be taken with the connection between the converter and the touch screen. Since resistive touch screens have fairly low resistance, the interconnection should be as short and robust as possible. Loose connections can be a source of error when the contact resistance changes with flexing or vibrations.

As indicated previously, noise can be a major source of error in touch-screen applications (e.g., applications that require a back-lit LCD panel). This EMI noise can be coupled through the LCD panel to the touch screen and cause *flickering* of the converted ADC data. Several things can be done to reduce this error, such as utilizing a touch screen with a bottom-side metal layer connected to ground. This couples the majority of noise to ground. Additionally, filtering capacitors, from Y+, Y–, X+, and X– to ground, can also help. Note, however, that the use of these capacitors increases screen settling time and require longer panel voltage stabilization times, as well as increased precharge and sense times for the PINTDAV circuitry of the TSC2101.

## CONVERSION TIME CALCULATIONS FOR THE TSC2101

### Touch Screen Conversion Initiated at Touch Detect

The time needed to get a converted X/Y coordinate for reading can be calculated by (not including the time needed to send the command over the SPI bus):

$$t_{\text{coordinate}} = 2 \times \left[ \frac{(t_{\text{PRE}} + t_{\text{SNS}} + t_{\text{PVS}})}{125 \text{ ns}} \right] \times t_{\text{OSC}} + 2 \times \left\{ N_{\text{AVG}} \left[ (N_{\text{BITS}} + 1) \times \frac{8 \text{ MHz}}{f_{\text{conv}}} + n_1 + 12 \right] + 1 \right\} \\ \times t_{\text{OSC}} + 18 \times t_{\text{OSC}} + n_2 \times t_{\text{OSC}} + n_3 \times t_{\text{OSC}}$$

where:

$t_{\text{coordinate}}$  = time to convert X/Y coordinate

$t_{\text{PVS}}$  = Panel voltage stabilization time

$t_{\text{PRE}}$  = precharge time

$t_{\text{SNS}}$  = sense time

$N_{\text{AVG}}$  = number of averages; for no averaging,  $N_{\text{AVG}} = 1$

$N_{\text{BITS}}$  = number of bits of resolution

$f_{\text{conv}}$  = A/D converter clock frequency

$t_{\text{OSC}}$  = Oscillator clock period

$n_1 = 6$  ; if  $f_{\text{conv}} = 8 \text{ MHz}$

7 ; if  $f_{\text{conv}} \neq 8 \text{ MHz}$

$n_2 = 4$  ; if  $t_{\text{PVS}} = 0 \mu\text{s}$

0 ; if  $t_{\text{PVS}} \neq 0 \mu\text{s}$

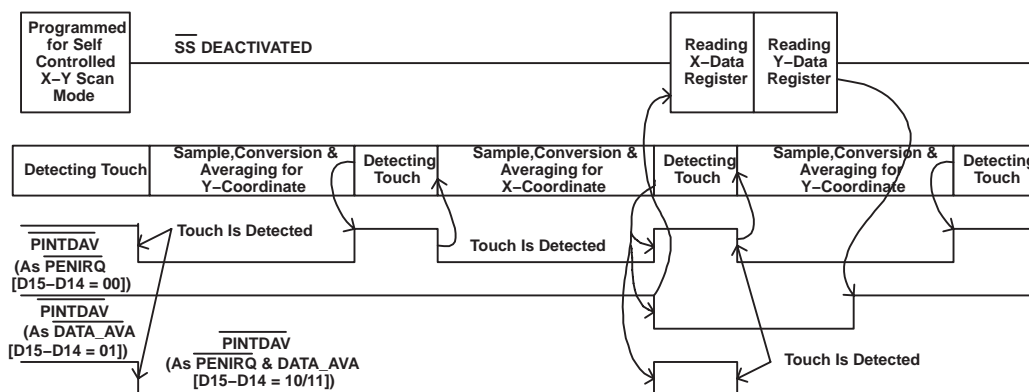

$n_3 = 0$  ; if  $t_{\text{SNS}} = 32 \mu\text{s}$

2 ; if  $t_{\text{SNS}} \neq 32 \mu\text{s}$

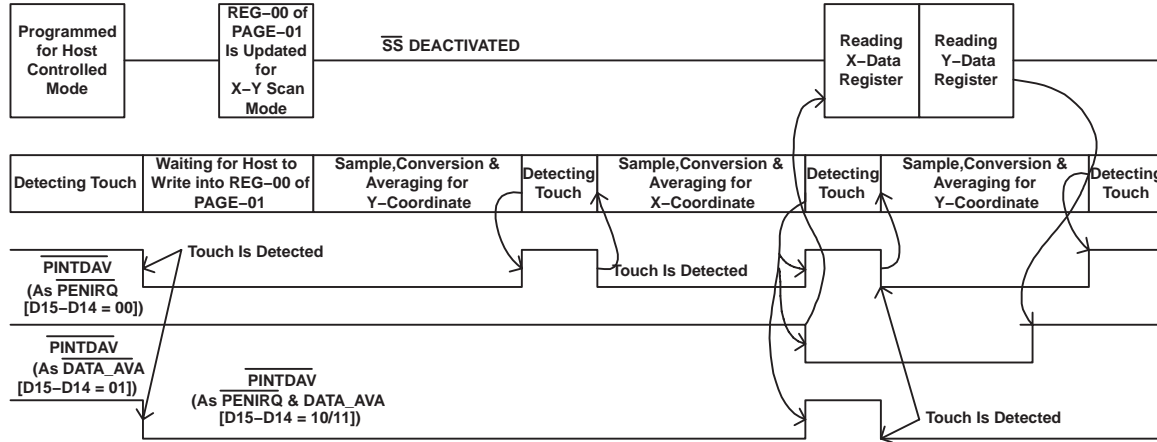

$t_{\text{PGDEL}}$  = Programmable delay in between conversion for touch screen measurement

= 0: if programmable delay mode is disabled for touch screen measurement

- (1)  $t_{\text{PGDEL}}$  delay is generated by using: Internal oscillator clock whose typical frequency is 1 MHz, in internal clock mode, or MCLK/CLKDIV (as programmed in control register 14H/page1) in external clock mode.
- (2) The above formula is valid exactly only when the codec is powered down. Also after touch detect the formula holds true from second conversion onwards.
- (3) If D15–D14 of control register 01H/page 1 = 00, then in case of continuous touch  $\overline{\text{PINTDAV}}$  remains high for  $(t_{\text{PRE}} + t_{\text{SNS}}) \times t_{\text{OSC}} / 125 \text{ ns}$ . If D15–D14 of control register 01H/page 1 = 10/11, then in case of continuous touch  $\overline{\text{PINTDAC}}$  remains high for  $(t_{\text{PRE}} + t_{\text{SNS}}) \times t_{\text{OSC}} / 125 \text{ ns} + t_{\text{PGDEL}}$ .

The time for a complete X/Y/Z1/Z2 coordinate conversion is given by(not including the time needed to send the command over the SPI bus):

$$t_{\text{coordinate}} = 3 \times \left[ \frac{(t_{\text{PRE}} + t_{\text{SNS}} + t_{\text{PVS}})}{125 \text{ ns}} \right] \times t_{\text{OSC}} + 4 \times \left\{ N_{\text{AVG}} \left[ (N_{\text{BITS}} + 1) \times \frac{8 \text{ MHz}}{f_{\text{conv}}} + n_1 + 12 \right] + 1 \right\} \\ \times t_{\text{OSC}} + 33 \times t_{\text{OSC}} + n_2 \times t_{\text{OSC}} + n_3 \times t_{\text{OSC}} + t_{\text{PGDEL}}$$

$$n_1 = 6 ; \text{ if } f_{\text{conv}} = 8 \text{ MHz}$$

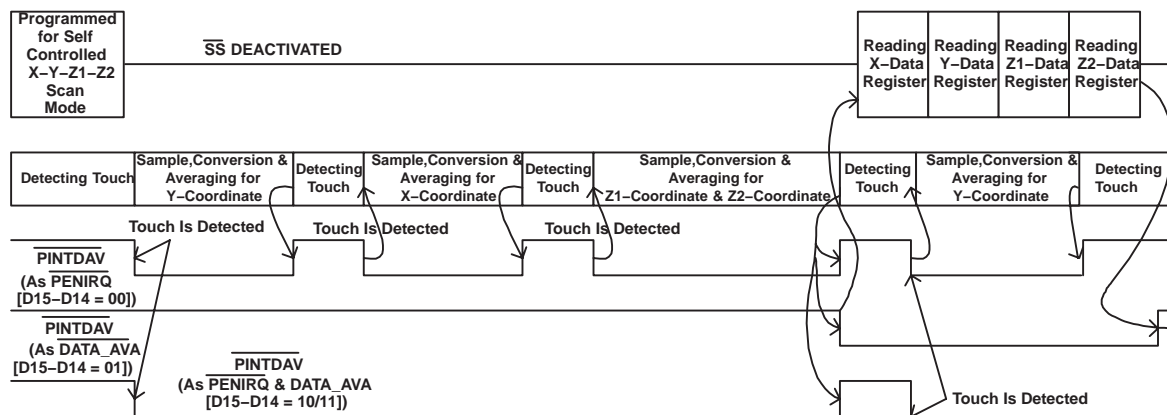

$$7 ; \text{ if } f_{\text{conv}} \neq 8 \text{ MHz}$$

$$n_2 = 4 ; \text{ if } t_{\text{PVS}} = 0 \mu\text{s}$$

$$0 ; \text{ if } t_{\text{PVS}} \neq 0 \mu\text{s}$$

$$n_3 = 0 ; \text{ if } t_{\text{SNS}} = 32 \mu\text{s}$$

$$3 ; \text{ if } t_{\text{SNS}} \neq 32 \mu\text{s}$$

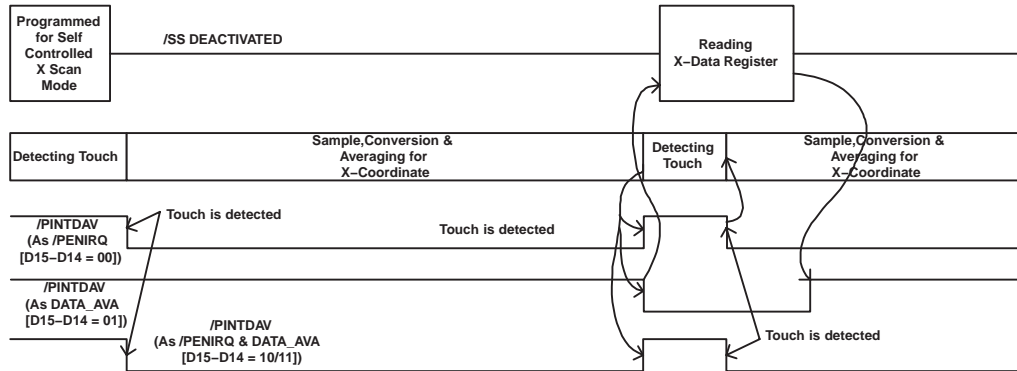

The time needed to convert any single coordinate either X or Y under self-controlled (not including the time needed to send the command over the SPI bus) is given by:

$$t_{\text{coordinate}} = \left[ \frac{(t_{\text{PRE}} + t_{\text{SNS}} + t_{\text{PVS}})}{125 \text{ ns}} \right] \times t_{\text{OSC}} + \left\{ N_{\text{AVG}} \left[ (N_{\text{BITS}} + 1) \times \frac{8 \text{ MHz}}{f_{\text{conv}}} + n_1 + 12 \right] + 1 \right\} \\ \times t_{\text{OSC}} + 16 \times t_{\text{OSC}} + n_2 \times t_{\text{OSC}} + n_3 \times t_{\text{OSC}} + t_{\text{PGDEL}}$$

$$n_1 = 6 ; \text{ if } f_{\text{conv}} = 8 \text{ MHz}$$

$$7 ; \text{ if } f_{\text{conv}} \neq 8 \text{ MHz}$$

- $n_2 = 2$  ; if  $t_{PVS} = 0 \mu s$
- 0 ; if  $t_{PVS} \neq 0 \mu s$
- $n_3 = 0$  ; if  $t_{SNS} = 32 \mu s$
- 0 ; if  $t_{SNS} \neq 32 \mu s$

The time needed to convert the Z coordinate under self-controlled mode (not including the time needed to send the command over the SPI bus) is given by:

$$t_{\text{coordinate}} = \left[ \frac{(t_{\text{PRE}} + t_{\text{SNS}} + t_{\text{PVS}})}{125 \text{ ns}} \right] \times t_{\text{OSC}} + 2 \times \left\{ N_{\text{AVG}} \left[ (N_{\text{BITS}} + 1) \times \frac{8 \text{ MHz}}{f_{\text{conv}}} + n_1 + 12 \right] + 1 \right\} \\
 \times t_{\text{OSC}} + 22 \times t_{\text{OSC}} + n_2 \times t_{\text{OSC}} + n_3 \times t_{\text{OSC}} + t_{\text{PGDEL}}$$

- $n_1 = 6$  ; if  $f_{\text{conv}} = 8 \text{ MHz}$
- 7 ; if  $f_{\text{conv}} \neq 8 \text{ MHz}$
- $n_2 = 2$  ; if  $t_{PVS} = 0 \mu s$
- 0 ; if  $t_{PVS} \neq 0 \mu s$
- $n_3 = 0$  ; if  $t_{SNS} = 32 \mu s$
- 1 ; if  $t_{SNS} \neq 32 \mu s$

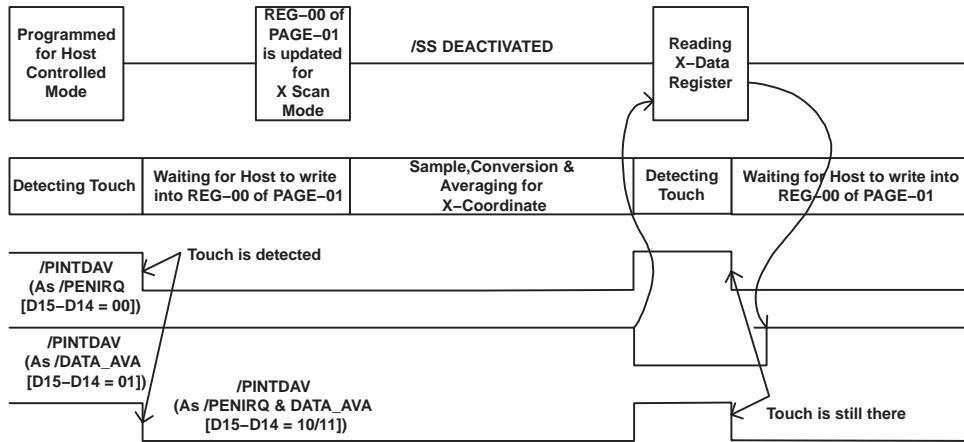

**Touch Screen Conversion Initiated by the Host**

The time needed to convert any single coordinate either X or Y under host-controlled mode (not including the time needed to send the command over the SPI bus) is given by:

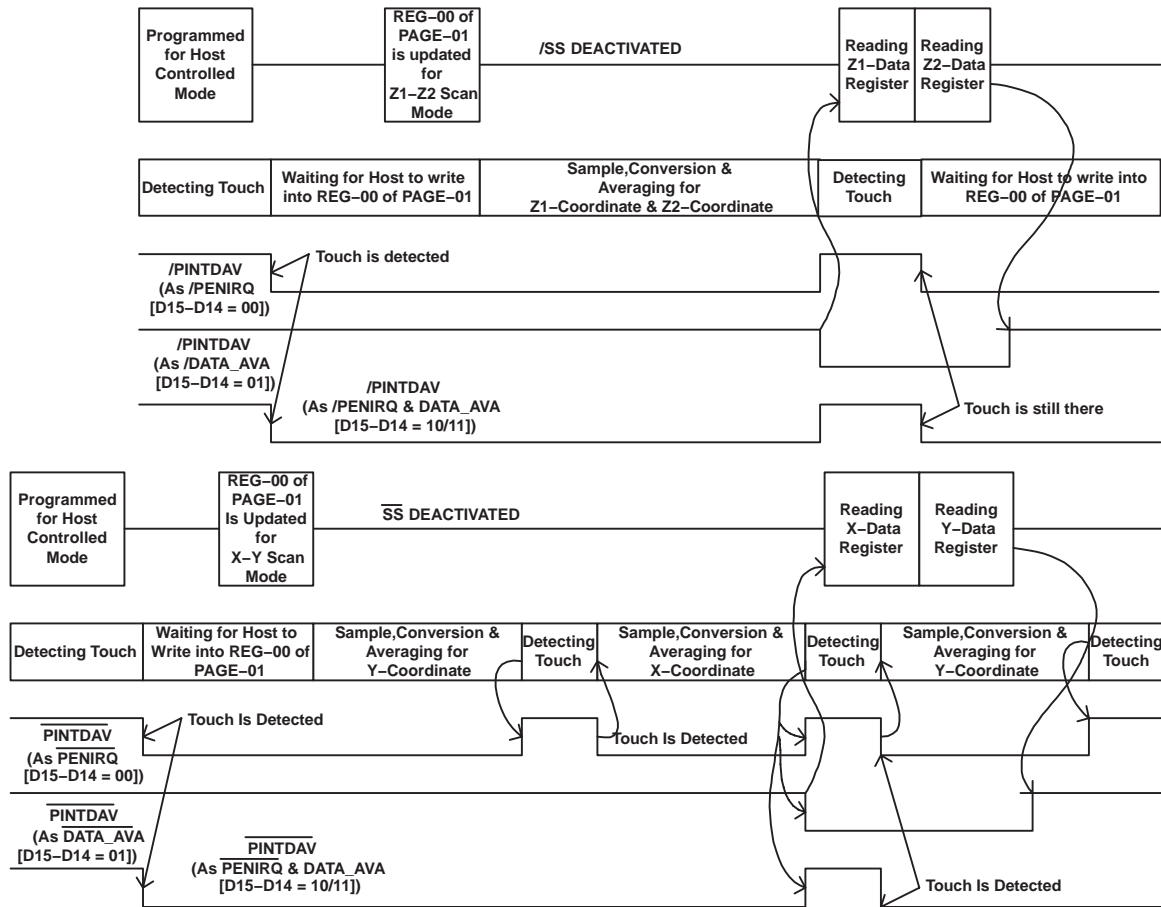

$$t_{\text{coordinate}} = \left[ \frac{t_{\text{PVS}}}{125 \text{ ns}} \right] \times t_{\text{OSC}} + \left\{ N_{\text{AVG}} \left[ \left( N_{\text{BITS}} + 1 \right) \times \frac{8 \text{ MHz}}{f_{\text{conv}}} + n_1 + 12 \right] + 1 \right\} \times t_{\text{OSC}} + 14 \times t_{\text{OSC}} + n_2 \times t_{\text{OSC}}$$

- $n_1 = 6$  ; if  $f_{\text{conv}} = 8 \text{ MHz}$
- 7 ; if  $f_{\text{conv}} \neq 8 \text{ MHz}$
- $n_2 = 2$  ; if  $t_{\text{PVS}} = 0 \mu\text{s}$
- 0 ; if  $t_{\text{PVS}} \neq 0 \mu\text{s}$

$$t_{\text{coordinate}} = \left[ \frac{t_{\text{PVS}}}{125 \text{ ns}} \right] \times t_{\text{OSC}} + 2 \times \left\{ N_{\text{AVG}} \left[ \left( N_{\text{BITS}} + 1 \right) \times \frac{8 \text{ MHz}}{f_{\text{conv}}} + n_1 + 12 \right] + 1 \right\} \times t_{\text{OSC}} + 20 \times t_{\text{OSC}} + n_2 \times t_{\text{OSC}}$$

- $n_1 = 6$  ; if  $f_{\text{conv}} = 8 \text{ MHz}$
- 7 ; if  $f_{\text{conv}} \neq 8 \text{ MHz}$
- $n_2 = 2$  ; if  $t_{\text{PVS}} = 0 \mu\text{s}$
- 0 ; if  $t_{\text{PVS}} \neq 0 \mu\text{s}$

### Non-Touch Screen Measurement Operation

The time needed to make temperature, auxiliary, or battery measurements is given by:

$$t = \left\{ N_{AVG} \left[ \left( N_{BITS} + 1 \right) \times \frac{8 \text{ MHz}}{f_{conv}} + n_1 + n_2 \right] + 1 \right\} \times t_{OSC} + 15 \times t_{OSC} + n_3 \times t_{OSC}$$

where:

$n_1 = 6$  ; if  $f_{conv} = 8 \text{ MHz}$

7 ; if  $f_{conv} \neq 8 \text{ MHz}$

$n_2 = 24$  ; if measurement is for TEMP1 case

12 ; if measurement is for other than TEMP1 case

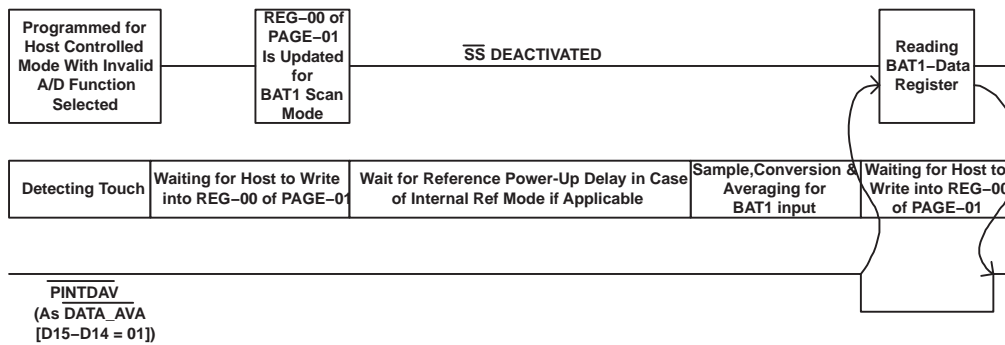

400 ns; if measurement is for the external/internal resistance using AUX1/AUX2

$n_3 = 0$  ; if external reference mode is selected

3 ; if  $t_{REF} = 0 \mu\text{s}$  or reference is programmed for power up all the time.

1 +  $t_{REF} / 125 \text{ ns}$ ; if  $t_{REF} \neq 0 \mu\text{s}$  and reference needs to power down between conversions.

$t_{REF}$  is the reference power up delay time.

The time needed for continuous autoscan mode is given by:

$$t = N_{INP} \times \left( \left\{ N_{AVG} \left[ \left( N_{BITS} + 1 \right) \times \frac{8 \text{ MHz}}{f_{conv}} + n_1 + 12 \right] + 1 \right\} \times t_{OSC} + 8 \times t_{OSC} \right) + n_2 \times t_{OSC} + t_{DEL} + n_3 \times t_{OSC} + n_4 \times t_{OSC}$$

where:

- $N_{INP} = 1$ ; if autoscan is selected for only one input AUX1, AUX2, TEMP1 or TEMP2
- $= 2$ ; if autoscan is selected for two inputs AUX1–AUX2, AUX1–TEMP1, AUX1–TEMP2 etc
- $= 3$ ; if autoscan is selected for three inputs AUX1–AUX2–TEMP1 or AUX1–AUX2–TEMP2
- $n_1 = 6$ ; if  $f_{conv} = 8 \text{ MHz}$
- $7$ ; if  $f_{conv} \neq 8 \text{ MHz}$
- $n_2 = 12$ ; if one of the input selected is TEMP1
- $0$ ; if measurement is for other than TEMP1
- $n_3 = 0$ ; if external reference mode is selected or  $t_{DEL} = 0$ .
- $3$ ; if  $t_{REF} = 0 \text{ ms}$  or reference is programmed for power up all the times.
- $1 + t_{REF}/125 \text{ ns}$ ; if  $t_{REF} \neq 0 \mu\text{s}$  and reference needs to power down between conversions.

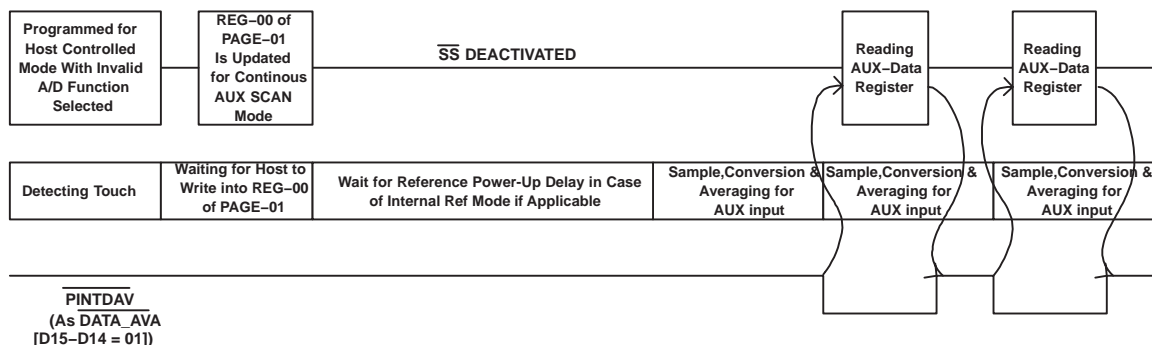

$t_{REF}$  is the reference power up delay time.

- $n_4 = 0$ ; if  $t_{DEL} = 0$ .
- $= 7$ ; if  $t_{DEL} \neq 0$

$t_{DEL} =$  Programmable delay in between conversion for nontouchscreen measurement  
 $= 0$ ; if programmable delay mode is disabled for nontouchscreen measurement

(1) The above equation is valid only from second conversion onwards.

(2)  $t_{DEL}$  delay is generated by using internal oscillator clock whose typical frequency is 1 MHz in internal clock mode, or MCLK/CLKDIV (as programmed in control register 14H/page 1) in external clock mode.

**Port Scan Operation**

The time needed to complete one set of port scan conversions is given by:

$$t_{\text{coordinate}} = 3 \times \left\{ N_{\text{AVG}} \left[ \left( N_{\text{BITS}} + 1 \right) \times \frac{8 \text{ MHz}}{f_{\text{conv}}} + n_1 + 12 \right] + 1 \right\} \times t_{\text{OSC}} + 31 \times t_{\text{OSC}} + n_2 \times t_{\text{OSC}}$$

where:

$n_1 = 6$  ; if  $f_{\text{conv}} = 8 \text{ MHz}$

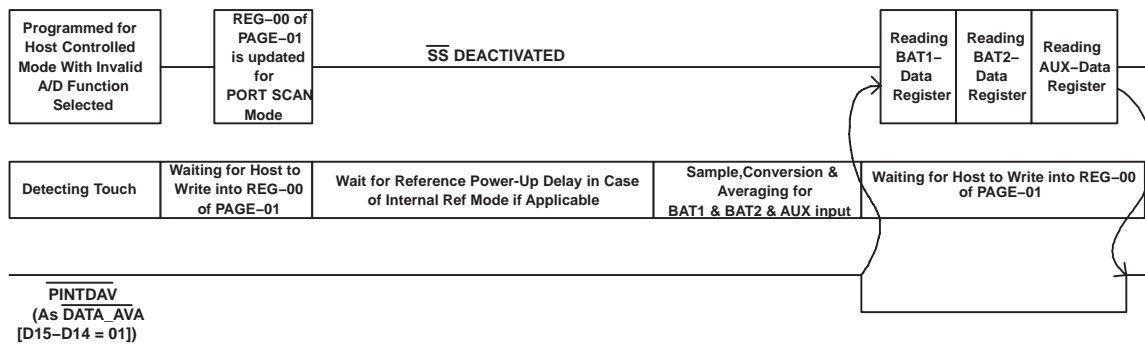

7 ; if  $f_{\text{conv}} \neq 8 \text{ MHz}$

$n_2 = 0$  ; if external reference mode is selected

3 ; if  $t_{\text{REF}} = 0 \mu\text{s}$  or reference is programmed for power up all the time.

1 +  $t_{\text{REF}} / 125 \text{ ns}$ ; if  $t_{\text{REF}} \neq 0 \mu\text{s}$  and reference needs to power down between conversions.

$t_{\text{REF}}$  is the reference power up delay time.

## PLL PROGRAMMING

The on-chip PLL in the TSC2101 can be used to generate sampling clocks from a wide range of MCLK's available in a system. The PLL works by generating oversampled clocks with respect to Fsref (44.1 kHz or 48 kHz). Frequency division generates all other internal clocks. Table 7 and Table 8 gives a sample programming for PLL registers for some standard MCLK's when PLL is required. Whenever the MCLK is of the form of  $N \times 128 \times \text{Fsref}$  ( $N=2,3,\dots$ ), the PLL is not required.

**Table 7. Fsref = 44.1 kHz**

| MCLK (MHz) | P | J  | D    | ACHIEVED FSREF | % ERROR |
|------------|---|----|------|----------------|---------|
| 2.8224     | 1 | 32 | 0    | 44100.00       | 0.0000  |
| 5.6448     | 1 | 16 | 0    | 44100.00       | 0.0000  |
| 12         | 1 | 7  | 5264 | 44100.00       | 0.0000  |
| 13         | 1 | 6  | 9474 | 44099.71       | 0.0007  |
| 16         | 1 | 5  | 6448 | 44100.00       | 0.0000  |
| 19.2       | 1 | 4  | 7040 | 44100.00       | 0.0000  |
| 19.68      | 1 | 4  | 5893 | 44100.30       | -0.0007 |
| 48         | 4 | 7  | 5264 | 44100.00       | 0.0000  |

**Table 8. Fsref = 48 kHz**

| MCLK (MHz) | P | J  | D    | ACHIEVED FSREF | % ERROR |
|------------|---|----|------|----------------|---------|
| 2.048      | 1 | 48 | 0    | 48000.00       | 0.0000  |

# MECHANICAL DATA

RGZ (S-PQFP-N48)

PLASTIC QUAD FLATPACK

4204101/E 11/04

- NOTES:
- A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994.
  - B. This drawing is subject to change without notice.
  - C. Quad Flatpack, No-leads (QFN) package configuration.
  - D. The package thermal pad must be soldered to the board for thermal and mechanical performance. See the Product Data Sheet for details regarding the exposed thermal pad dimensions.
  - E. Falls within JEDEC MO-220.

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.
