

MAXIM

Ultra-Small, +1.8V, μ Power, Rail-to-Rail I/O Op Amps

MAX4291/MAX4292/MAX4294

General Description

The MAX4291/MAX4292/MAX4294 family of micropower operational amplifiers operates from a +1.8V to +5.5V single supply or $\pm 0.9V$ to $\pm 2.75V$ dual supplies and has Rail-to-Rail® input/output capabilities. These amplifiers provide a 500kHz gain-bandwidth product and 120dB open-loop voltage gain while using only 100 μ A of supply current per amplifier. The combination of low input offset voltage ($\pm 400\mu$ V) and high-open-loop gain makes them suitable for low-power/low-voltage high-precision applications.

The MAX4291/MAX4292/MAX4294 have an input common-mode range that extends to each supply rail, and their outputs typically swing within 20mV of the rails with a 2k Ω load. Although the minimum operating voltage is specified at +1.8V, these devices typically operate down to +1.5V. The combination of ultra-low-voltage operation, rail-to-rail inputs/output, and low-power consumption makes these devices ideal for any portable/two-cell battery-powered system.

The single MAX4291 is offered in an ultra-small 5-pin SC70 package and the dual MAX4292 is offered in a space-saving 8-pin μ MAX package.

Applications

- 2-Cell Battery-Operated Systems
- Portable Electronic Equipment
- Battery-Powered Instrumentation
- Digital Scales
- Strain Gauges
- Sensor Amplifiers
- Cellular Phones

Selector Guide

PART	AMPLIFIERS PER PACKAGE	PIN-PACKAGE
MAX4291	1	5-pin SC70/SOT23
MAX4292	2	8-pin μ MAX/SO
MAX4294	4	14-pin SO/TSSOP

Features

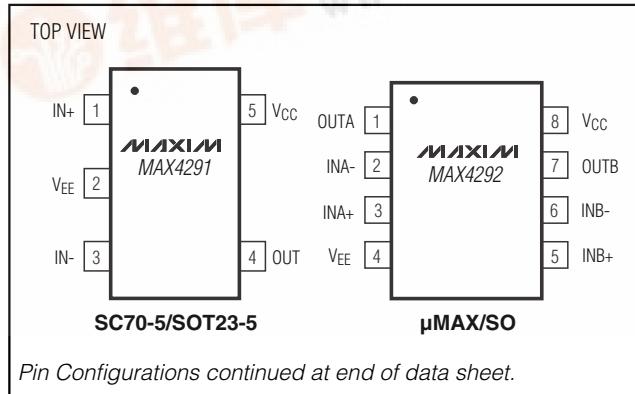

- ♦ Ultra-Low Voltage Operation—Guaranteed Down to +1.8V
- ♦ 100 μ A Supply Current per Amplifier
- ♦ 500kHz Gain-Bandwidth Product
- ♦ 120dB Open-Loop Voltage Gain ($R_L = 100\text{k}\Omega$)
- ♦ 0.017% THD + Noise at 1kHz
- ♦ Rail-to-Rail Input Common-Mode Range
- ♦ Rail-to-Rail Output Drives 2k Ω Load
- ♦ No Phase Reversal for Overdriven Inputs
- ♦ Unity-Gain Stable for Capacitive Loads up to 100pF
- ♦ 400 μ V Input Offset Voltage
- ♦ Single Available in Ultra-Small 5-Pin SC70
Dual Available in Space-Saving 8-Pin μ MAX

Detailed Description

Rail-to-Rail Input Stage

The MAX4291/MAX4292/MAX4294 have rail-to-rail inputs and output stages that are specifically designed for low-voltage, single-supply operation. The input stage consists of separate NPN and PNP differential stages, which operate together to provide a common-mode range extending to both supply rails. The crossover region of these two pairs occurs halfway between V_{CC} and V_{EE}. The input offset voltage is typically $\pm 400\mu\text{V}$. Low operating supply voltage, low supply current, rail-to-rail common-mode input range, and rail-to-rail outputs make this family of operational amplifiers (op amps) an excellent choice for precision or general-purpose, low-voltage, battery-powered systems.

Since the input stage consists of NPN and PNP pairs, the input bias current changes polarity as the common-mode voltage passes through the crossover region. Match the effective impedance seen by each input to reduce the offset error caused by input bias currents flowing through external source impedances (Figures 1a and 1b).

The combination of high source impedance plus input capacitance (amplifier input capacitance plus stray capacitance) creates a parasitic pole that produces an underdamped signal response. Reducing input capacitance or placing a small capacitor across the feedback resistor improves response in this case.

Lithium-Ion (1 cell)	Yes	3.5	2.7	1000	10,000
Nickel-Metal-Hydride (2 cells)	Yes	2.4	1.8	1000	10,000

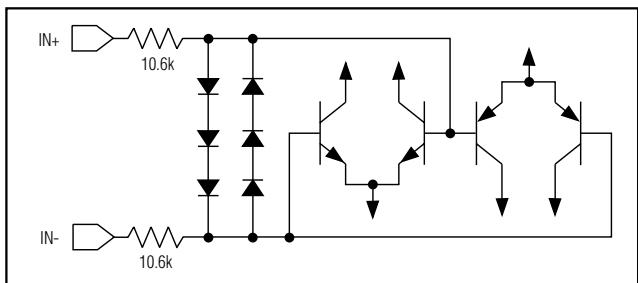

Figure 2. Input Protection Circuit

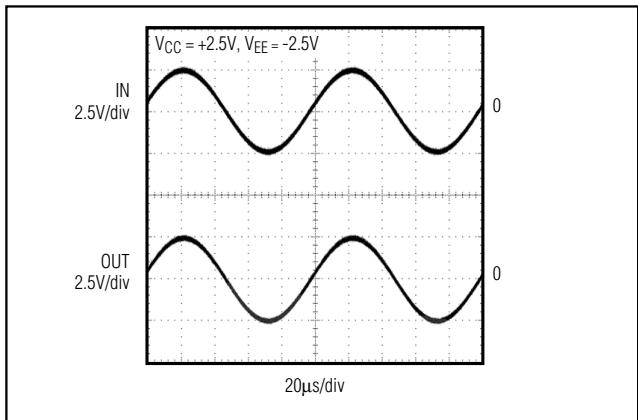

Figure 3. Rail-to-Rail Input/Output Voltage Range

The MAX4291/MAX4292/MAX4294 family's inputs are protected from large differential input voltages by internal 10.6k Ω series resistors and back-to-back triple-diode stacks across the inputs (Figure 2). For differential input voltages (much less than 1.8V), input resistance is typically 0.75M Ω . For differential input voltages greater than 1.8V, input resistance is around 21.2k Ω , and the input bias current can be approximated by the following equation:

$$I_{BIAS} = \frac{(V_{DIFF} - 1.8V)}{21.2k\Omega}$$

In the region where the differential input voltage approaches 1.8V, the input resistance decreases exponentially from 0.75M Ω to 21.2k Ω as the diode block begins to conduct. Conversely, the bias current increases with the same curve.

In unity-gain configuration, high slew rate input signals may capacitively couple to the output through the triple-diode stacks.

Rail-to-Rail Output Stage

The MAX4291/MAX4292/MAX4294 output stage can drive up to a 2k Ω load and still swing to within 20mV of the rails. Figure 3 shows the output voltage swing of a MAX4291 configured as a unity-gain buffer, powered from a $\pm 2.5V$ supply. The output for this setup typically swings from $(V_{EE} + 3mV)$ to $(V_{CC} - 2mV)$ with a 100k Ω load.

Applications Information

Power-Supply Considerations

The MAX4291/MAX4292/MAX4294 operate from a single +1.8V to +5.5V supply (or dual $\pm 0.9V$ to $\pm 2.75V$ supplies) and consume only 100 μ A of supply current per amplifier. A high power-supply rejection ratio of 80dB allows the amplifiers to be powered directly off a decaying battery voltage, simplifying design and extending battery life.

The MAX4291/MAX4292/MAX4294 are ideally suited for use with most battery-powered systems. Table 1 lists a variety of typical battery types showing voltage when fresh, voltage at end-of-life, capacity, and approximate operating time from a MAX4291 (assuming nominal conditions).

Ultra-Small, +1.8V, μ Power, Rail-to-Rail I/O Op Amps

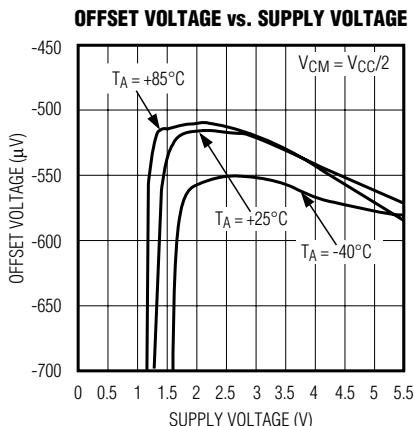

Figure 4. Offset Voltage vs. Supply Voltage

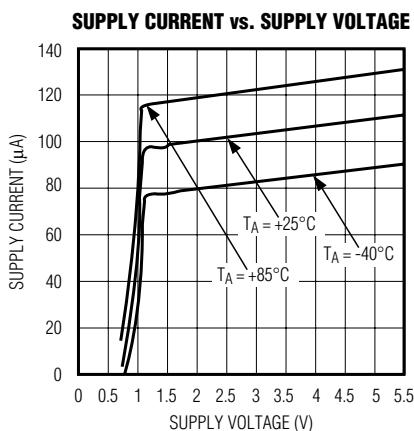

Figure 5. Supply Current vs. Supply Voltage

Although the amplifiers are fully guaranteed over temperature for operation down to a +1.8V single supply, even lower voltage operation is possible in practice. Figures 4 and 5 show the offset voltage and supply current as a function of supply voltage and temperature.

Load-Driving Capability

The MAX4291/MAX4292/MAX4294 are fully guaranteed over temperature and supply voltage range to drive a maximum resistive load of $2k\Omega$ to $V_{CC}/2$, although heavier loads can be driven in many applications. The rail-to-rail output stage of the amplifier can be modeled as a current source when driving the load toward V_{CC} , and as a current sink when driving the load toward V_{EE} . The limit of this current source/sink varies with supply voltage, ambient temperature, and lot-to-lot variations of the units.

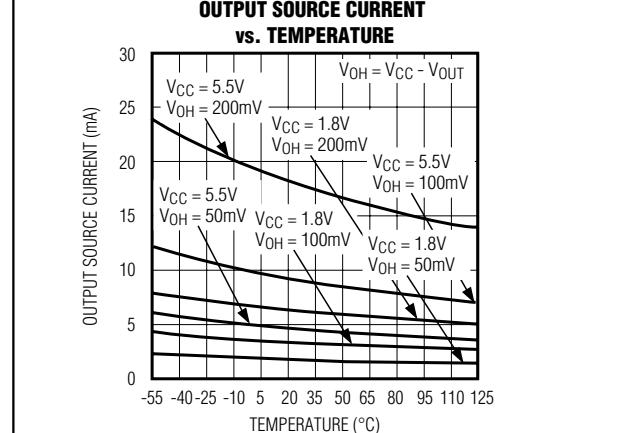

Figure 6a. Output Source Current vs. Temperature

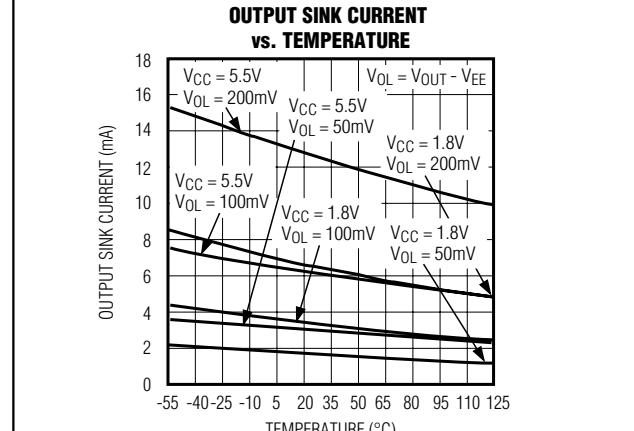

Figure 6b. Output Sink Current vs. Temperature

Figures 6a and 6b show the typical current source and sink capabilities of the MAX4291/MAX4292/MAX4294 family as a function of supply voltage and ambient temperature. The contours on the graph depict the output current value, based on driving the output voltage to within 50mV, 100mV, and 200mV of either power-supply rail.

For example, a MAX4291 running from a single +1.8V supply, operating at $T_A = +25^\circ C$ can source 3.5mA to within 100mV of V_{CC} and is capable of driving a 485Ω load resistor to V_{EE} :

$$R_L = \frac{(1.8V - 0.1V)}{3.5mA} = 485\Omega \text{ to } V_{EE}$$

The same application can drive a $220k\Omega$ load resistor when terminated in $V_{CC}/2$ (+0.9V in this case).

Ultra-Small, +1.8V, μ Power, Rail-to-Rail I/O Op Amps

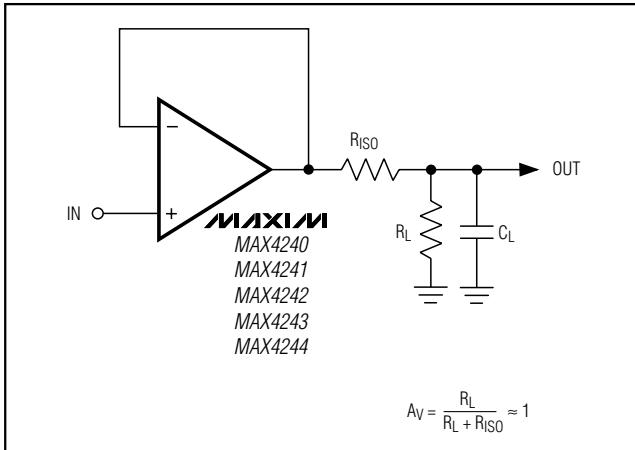

Figure 7a. Using a Resistor to Isolate a Capacitive Load from the Op Amp

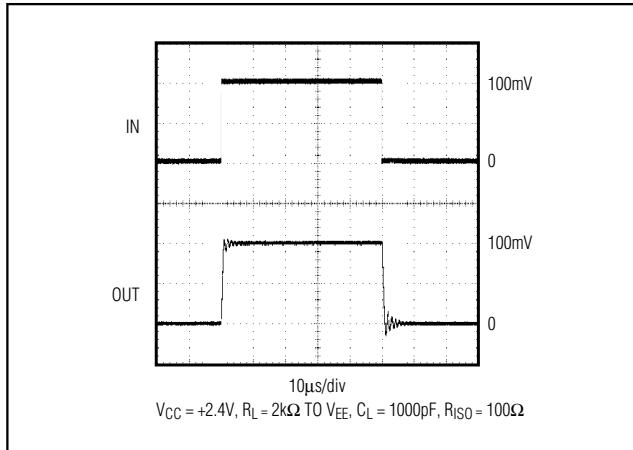

Figure 7c. Pulse Response with Isolating Resistor (100 Ω)

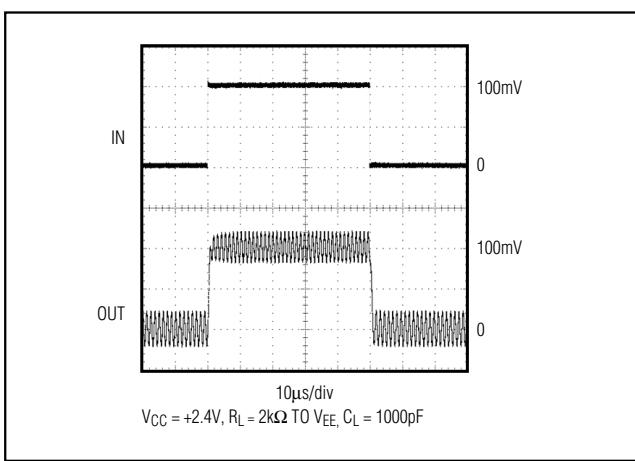

Figure 7b. Pulse Response Without Isolating Resistor

Driving Capacitive Loads

The MAX4291/MAX4292/MAX4294 are unity-gain stable for loads up to 100pF (see the Load Resistor vs. Capacitive Load graph in the *Typical Operating Characteristics*). Applications that require greater capacitive drive capability should use an isolation resistor between the output and the capacitive load (Figure 7). Note that this alternative results in a loss of gain accuracy because R_{ISO} forms a voltage divider with the load resistor.

Power-Supply Bypassing and Layout

The MAX4291/MAX4292/MAX4294 family operates from either a single +1.8V to +5.5V supply or dual $\pm 0.9V$ to $\pm 2.75V$ supplies. For single-supply operation, bypass the power supply with a 100nF capacitor to V_{EE} (in this case GND). For dual-supply operation, both the V_{CC}

and the V_{EE} supplies should be bypassed to ground with separate 100nF capacitors.

Good PC board layout techniques optimize performance by decreasing the amount of stray capacitance at the op amp's inputs and output. To decrease stray capacitance, minimize trace lengths and widths by placing external components as close as possible to the op amp. Surface-mount components are an excellent choice.

Using the MAX4291/MAX4292/MAX4294 as Comparators

Although optimized for use as operational amplifiers, the MAX4291/MAX4292/MAX4294 can also be used as rail-to-rail I/O comparators. Typical propagation delay depends on the input overdrive voltage, as shown in Figure 8. External hysteresis can be used to minimize the risk of output oscillation. The positive feedback circuit, shown in Figure 9, causes the input threshold to change when the output voltage changes state. The two thresholds create a hysteresis band that can be calculated by the following equations:

$$V_{HYST} = V_{HI} - V_{LO}$$

$$V_{HI} = \left[1 + \frac{R_1}{R_2} + \frac{R_1}{R_{HYST}} \right] V_{REF}$$

$$V_{LO} = V_{HI} - \left(\frac{R_1}{R_{HYST}} \right) V_{CC}$$

When the output of the comparator is low, the supply current increases. The output stage has biasing circuitry to monitor the output current. When the amplifier is

Ultra-Small, +1.8V, μ Power, Rail-to-Rail I/O Op Amps

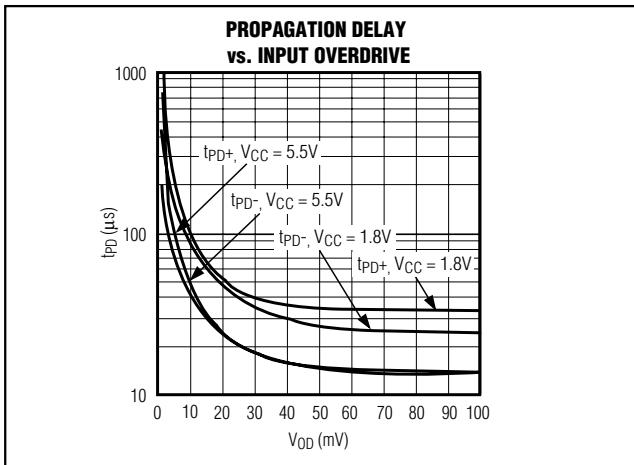

Figure 8. Propagation Delay vs. Input Overdrive

used as a comparator, the output stage is overdriven and the current through the biasing circuitry increases to maximum. For the MAX4291, typical supply currents increase to 1.5mA with $V_{CC} = 1.8V$ and to 9mA when $V_{CC} = 5.0V$ (Figure 10).

Using the MAX4291/MAX4292/MAX4294 as Low-Power Current Monitors

The MAX4291/MAX4292/MAX4294 are ideal for applications powered from a two-cell battery stack. Figure 11 shows an application circuit in which the MAX4291 is used for monitoring the current of a two-cell battery stack. In this circuit, a current load is applied, and the voltage drop at the battery terminal is sensed.

The voltage on the load side of the battery stack is equal to the voltage at the emitter of Q1 due to the feedback loop containing the op amp. As the load current increases, the voltage drop across R1 and R2 increases. Thus, R2 provides a fraction of the load current (set by the ratio of R1 and R2) that flows into the emitter of the PNP transistor. Neglecting PNP base current, this current flows into R3, producing a ground-referenced voltage proportional to the load current. To minimize errors, scale R1 to give a voltage drop that is large enough in comparison to the op amp's V_{OS} .

Calculate the output voltage of the application using the following equation:

$$V_{OUT} = \left[I_{LOAD} \times \left(\frac{R_1}{R_2} \right) \right] \times R_3$$

For a 1V output and a current load of 50mA, the choice of resistors can be $R_1 = 2\Omega$, $R_2 = 100k\Omega$, and $R_3 = 1M\Omega$.
