# MAX660 Switched Capacitor Voltage Converter

## General Description

The MAX660 CMOS charge-pump voltage converter inverts a positive voltage in the range of 1.5V to 5.5V to the corresponding negative voltage. The MAX660 uses two low cost capacitors to provide 100 mA of output current without the cost, size, and EMI related to inductor based converters. With an operating current of only 120  $\mu$ A and operating efficiency greater than 90% at most loads, the MAX660 provides ideal performance for battery powered systems. The MAX660 may also be used as a positive voltage doubler.

The oscillator frequency can be lowered by adding an external capacitor to the OSC pin. Also, the OSC pin may be used to drive the MAX660 with an external clock. A frequency control (FC) pin selects the oscillator frequency of 10 kHz or 80 kHz.

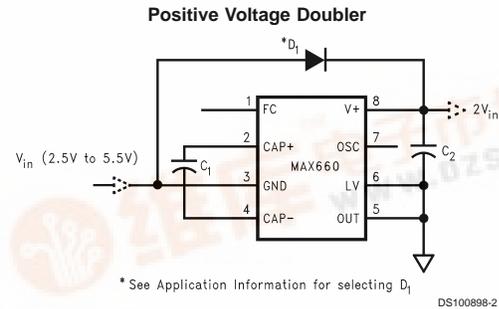

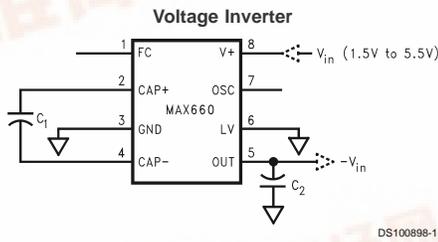

## Features

- Inverts or doubles input supply voltage
- Narrow SO-8 Package
- 6.5 $\Omega$  typical output resistance
- 88% typical conversion efficiency at 100 mA
- Selectable oscillator frequency: 10 kHz/80 kHz

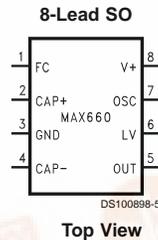

## Applications

- Laptop computers
- Cellular phones
- Medical instruments
- Operational amplifier power supplies
- Interface power supplies
- Handheld instruments

## Typical Application Circuits

## Connection Diagram

## Ordering Information

Order Number	Top Mark	Package	Supplied as
MAX660M	Date Code MAX660M	M08A	Rail (95 units/rail)
MAX660MX	Date Code MAX660M	M08A	Tape and Reel (2500 units/rail)

MAX660 Switched Capacitor Voltage Converter

**Absolute Maximum Ratings** (Note 1)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/ Distributors for availability and specifications.

Supply Voltage (V+ to GND, or GND to OUT)	6V
LV	(OUT – 0.3V) to (GND + 3V)
FC, OSC	The least negative of (OUT – 0.3V) or (V+ – 6V) to (V+ + 0.3V)
V+ and OUT Continuous Output Current	120 mA
Output Short-Circuit Duration to GND (Note 2)	1 sec.

Power Dissipation

( $T_A = 25^\circ\text{C}$ ) (Note 3)	735 mW
$T_J$ Max (Note 3)	150°C
$\theta_{JA}$ (Note 3)	170°C/W
Operating Junction Temp. Range	–40°C to +85°C
Storage Temperature Range	–65°C to +150°C
Lead Temperature (Soldering, 10 seconds)	300°C
ESD Rating	2 kV

**Electrical Characteristics**

Limits in standard typeface are for  $T_J = 25^\circ\text{C}$ , and limits in **boldface** type apply over the full operating temperature range. Unless otherwise specified: V+ = 5V, FC = Open,  $C_1 = C_2 = 150\ \mu\text{F}$ . (Note 4)

Symbol	Parameter	Condition	Min	Typ	Max	Units
V+	Supply Voltage	$R_L = 1\text{k}$ Inverter, LV = Open (Note 5)	<b>3.5</b>		<b>5.5</b>	V
			<b>1.5</b>		<b>5.5</b>	
			<b>2.5</b>		<b>5.5</b>	
$I_Q$	Supply Current	No Load LV = Open	FC = Open	0.12	<b>0.5</b>	mA
			FC = V+	1	<b>3</b>	
$I_L$	Output Current	$T_A \leq +85^\circ\text{C}$ , OUT $\leq -4\text{V}$ $T_A > +85^\circ\text{C}$ , OUT $\leq -3.8\text{V}$	<b>100</b>			mA
			<b>100</b>			
$R_{OUT}$	Output Resistance (Note 6)	$I_L = 100\text{ mA}$	$T_A \leq +85^\circ\text{C}$	6.5	<b>10</b>	$\Omega$
			$T_A > +85^\circ\text{C}$		<b>12</b>

			<b>92</b>	96		
				88		
$V_{OEFF}$	Voltage Conversion Efficiency	No Load	<b>99</b>	99.96		%

**Note 1:** Absolute maximum ratings indicate limits beyond which damage to the device may occur. Electrical specifications do not apply when operating the device beyond its rated operating conditions.

**Note 2:** OUT may be shorted to GND for one second without damage. However, shorting OUT to V+ may damage the device and should be avoided. Also, for temperatures above 85°C, OUT must not be shorted to GND or V+, or device may be damaged.

**Note 3:** The maximum allowable power dissipation is calculated by using  $P_{DMax} = (T_{JMax} - T_A)/\theta_{JA}$ , where  $T_{JMax}$  is the maximum junction temperature,  $T_A$  is the ambient temperature, and  $\theta_{JA}$  is the junction-to-ambient thermal resistance of the specified package.

**Note 4:** In the test circuit, capacitors  $C_1$  and  $C_2$  are 0.2 $\Omega$  maximum ESR capacitors. Capacitors with higher ESR will increase output resistance, reduce output voltage and efficiency.

**Note 5:** The minimum limit for this parameter is different from the limit of 3.0V for the industry-standard "660" product. For inverter operation with supply voltage below 3.5V, connect the LV pin to GND.

**Note 6:** Specified output resistance includes internal switch resistance and capacitor ESR.

## Pin Description

Pin	Name	Function	
		Voltage Inverter	Voltage Doubler
1	FC	Frequency control for internal oscillator: FC = open, $f_{OSC} = 10 \text{ kHz (typ)}$ ; FC = V+, $f_{OSC} = 80 \text{ kHz (typ)}$ ; FC has no effect when OSC pin is driven externally.	Same as inverter.
2	CAP+	Connect this pin to the positive terminal of charge-pump capacitor.	Same as inverter.
3	GND	Power supply ground input.	Power supply positive voltage input.
4	CAP-	Connect this pin to the negative terminal of charge-pump capacitor.	Same as inverter.
5	OUT	Negative voltage output.	Power supply ground input.
6	LV	Low-voltage operation input. Tie LV to GND when input voltage is less than 3.5V. Above 3.5V, LV can be connected to GND or left open. When driving OSC with an external clock, LV must be connected to GND.	LV must be tied to OUT.
7	OSC	Oscillator control input. OSC is connected to an internal 15 pF capacitor. An external capacitor can be connected to slow the oscillator. Also, an external clock can be used to drive OSC.	Same as inverter except that OSC cannot be driven by an external clock.
8	V+	Power supply positive voltage input.	Positive voltage output.

## Circuit Description

The MAX660 contains four large CMOS switches which are switched in a sequence to invert the input supply voltage. Energy transfer and storage are provided by external capacitors. *Figure 2* illustrates the voltage conversion scheme. When  $S_1$  and  $S_3$  are closed,  $C_1$  charges to the supply voltage  $V+$ . During this time interval switches  $S_2$  and  $S_4$  are open. In the second time interval,  $S_1$  and  $S_3$  are open and  $S_2$  and  $S_4$  are closed,  $C_1$  is charging  $C_2$ . After a number of cycles, the voltage across  $C_2$  will be pumped to  $V+$ . Since the anode of  $C_2$  is connected to ground, the output at the cathode of  $C_2$  equals  $-(V+)$  assuming no load on  $C_2$ , no loss in the switches, and no ESR in the capacitors. In reality, the charge transfer efficiency depends on the switching frequency, the on-resistance of the switches, and the ESR of the capacitors.

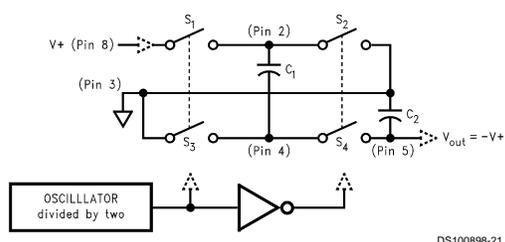

FIGURE 2. Voltage Inverting Principle

## Application Information

### SIMPLE NEGATIVE VOLTAGE CONVERTER

The main application of MAX660 is to generate a negative supply voltage. The voltage inverter circuit uses only two external capacitors as shown in the Typical Application Circuits. The range of the input supply voltage is 1.5V to 5.5V. For a supply voltage less than 3.5V, the LV pin must be connected to ground to bypass the internal regulator circuitry. This gives the best performance in low voltage applications. If the supply voltage is greater than 3.5V, LV may be connected to ground or left open. The choice of leaving LV open simplifies the direct substitution of the MAX660 for the LMC7660 Switched Capacitor Voltage Converter.

The output characteristics of this circuit can be approximated by an ideal voltage source in series with a resistor. The voltage source equals  $-(V+)$ . The output resistance  $R_{out}$  is a function of the ON resistance of the internal MOS switches, the oscillator frequency, and the capacitance and ESR of  $C_1$  and  $C_2$ . A good approximation is:

$$R_{out} \cong 2R_{SW} + \frac{2}{f_{osc} \times C_1} + 4ESR_{C1} + ESR_{C2}$$

where  $R_{SW}$  is the sum of the ON resistance of the internal MOS switches shown in *Figure 2*.

High value, low ESR capacitors will reduce the output resistance. Instead of increasing the capacitance, the oscillator frequency can be increased to reduce the  $2/(f_{osc} \times C_1)$  term. Once this term is trivial compared with  $R_{SW}$  and ESRs, further increasing in oscillator frequency and capacitance will become ineffective.

The peak-to-peak output voltage ripple is determined by the oscillator frequency, and the capacitance and ESR of the output capacitor  $C_2$ :

**Application Information** (Continued)

$$V_{ripple} = \frac{I_L}{f_{osc} \times C_2} + 2 \times I_L \times ESR_{C2}$$

Again, using a low ESR capacitor will result in lower ripple.

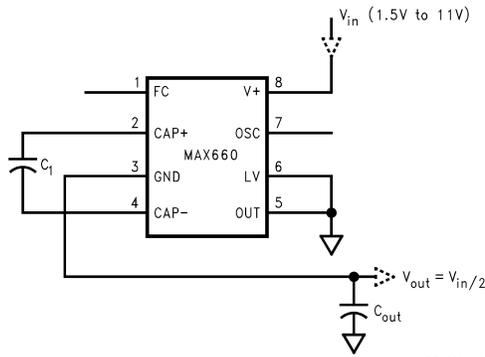

**POSITIVE VOLTAGE DOUBLER**

The MAX660 can operate as a positive voltage doubler (as shown in the Typical Application Circuits). The doubling function is achieved by reversing some of the connections to the device. The input voltage is applied to the GND pin with an allowable voltage from 2.5V to 5.5V. The V+ pin is used as the output. The LV pin and OUT pin must be connected to ground. The OSC pin can not be driven by an external clock in this operation mode. The unloaded output voltage is twice of the input voltage and is not reduced by the diode D<sub>1</sub>'s forward drop.

The Schottky diode D<sub>1</sub> is only needed for start-up. The internal oscillator circuit uses the V+ pin and the LV pin (connected to ground in the voltage doubler circuit) as its power rails. Voltage across V+ and LV must be larger than 1.5V to insure the operation of the oscillator. During start-up, D<sub>1</sub> is used to charge up the voltage at V+ pin to start the oscillator; also, it protects the device from turning-on its own parasitic diode and potentially latching-up. Therefore, the Schottky diode D<sub>1</sub> should have enough current carrying capability to charge the output capacitor at start-up, as well as a low forward voltage to prevent the internal parasitic diode from turning-on. A Schottky diode like 1N5817 can be used for most applications. If the input voltage ramp is less than 10V/ms, a smaller Schottky diode like MBR0520LT1 can be used to reduce the circuit size.

**SPLIT V+ IN HALF**

Another interesting application shown in the Basic Application Circuits is using the MAX660 as a precision voltage divider. Since the off-voltage across each switch equals V<sub>IN</sub>/2, the input voltage can be raised to +11V.

**FIGURE 3. Splitting V<sub>IN</sub> in Half**

**CHANGING OSCILLATOR FREQUENCY**

The internal oscillator frequency can be selected using the Frequency Control (FC) pin. When FC is open, the oscillator frequency is 10 kHz; when FC is connected to V+, the frequency increases to 80 kHz. A higher oscillator frequency al-

lows smaller capacitors to be used for equivalent output resistance and ripple, but increases the typical supply current from 0.12 mA to 1 mA.

The oscillator frequency can be lowered by adding an external capacitor between OSC and GND. (See Typical Performance Characteristics.) Also, in the inverter mode, an external clock that swings within 100 mV of V+ and GND can be used to drive OSC. Any CMOS logic gate is suitable for driving OSC. LV must be grounded when driving OSC. The maximum external clock frequency is limited to 150 kHz.

The switching frequency of the converter (also called the charge pump frequency) is half of the oscillator frequency.

**Note:** OSC cannot be driven by an external clock in the voltage-doubling mode.

**TABLE 1. MAX660 Oscillator Frequency Selection**

FC	OSC	Oscillator
Open	Open	10 kHz
V+	Open	80 kHz
Open or V+	External Capacitor	See Typical Performance Characteristics
N/A	External Clock (inverter mode only)	External Clock Frequency

**CAPACITOR SELECTION**

As discussed in the *Simple Negative Voltage Converter* section, the output resistance and ripple voltage are dependent on the capacitance and ESR values of the external capacitors. The output voltage drop is the load current times the output resistance, and the power efficiency is

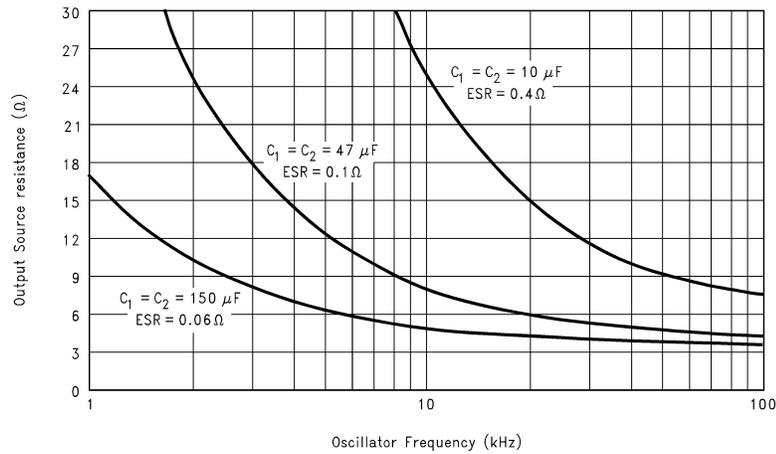

$$\eta = \frac{P_{out}}{P_{in}} = \frac{I_L^2 R_L}{I_L^2 R_L + I_L^2 R_{out} + I_Q (V+)}$$

Where I<sub>Q</sub>(V+) is the quiescent power loss of the IC device, and I<sub>L</sub><sup>2</sup>R<sub>OUT</sub> is the conversion loss associated with the switch on-resistance, the two external capacitors and their ESRs.

Since the switching current charging and discharging C<sub>1</sub> is approximately twice as the output current, the effect of the ESR of the pumping capacitor C<sub>1</sub> is multiplied by four in the output resistance. The output capacitor C<sub>2</sub> is charging and discharging at a current approximately equal to the output current, therefore, its ESR only counts once in the output resistance. However, the ESR of C<sub>2</sub> directly affects the output voltage ripple. Therefore, low ESR capacitors (Table 2) are recommended for both capacitors to maximize efficiency, reduce the output voltage drop and voltage ripple. For convenience, C<sub>1</sub> and C<sub>2</sub> are usually chosen to be the same.

The output resistance varies with the oscillator frequency and the capacitors. In Figure 4, the output resistance vs. oscillator frequency curves are drawn for three different tantalum capacitors. At very low frequency range, capacitance plays the most important role in determining the output resistance. Once the frequency is increased to some point (such as 20 kHz for the 150 μF capacitors), the output resistance is dominated by the ON resistance of the internal switches and the ESRs of the external capacitors. A low value, smaller size capacitor usually has a higher ESR compared with a bigger size capacitor of the same type. For lower ESR, use ceramic capacitors.

**Application Information** (Continued)

**FIGURE 4. Output Source Resistance vs Oscillator Frequency**

Sanyo	(619)-661-6835	(619)-661-1055	OS-CON series, through-hole aluminum electrolytic

**Other Applications**

**PARALLELING DEVICES**

Any number of MAX660s can be paralleled to reduce the output resistance. Each device must have its own pumping capacitor  $C_1$ , while only one output capacitor  $C_{out}$  is needed as shown in Figure 5. The composite output resistance is:

$$R_{out} = \frac{R_{out \text{ of each MAX660}}}{\text{Number of Devices}}$$

**FIGURE 5. Lowering Output Resistance by Paralleling Devices**

**CASCADING DEVICES**

Cascading the is an easy way to produce a greater negative voltage (as shown in Figure 6). If  $n$  is the integer representing the number of devices cascaded, the unloaded output voltage  $V_{out}$  is  $(-nV_{in})$ . The effective output resistance is equal to the weighted sum of each individual device:

$$R_{out} = nR_{out\_1} + \frac{n}{2}R_{out\_2} + \dots + R_{out\_n}$$

### Other Applications (Continued)

A three-stage cascade circuit shown in Figure 7 generates  $-3V_{in}$  from  $V_{in}$ . Cascading is also possible when devices are operating in doubling mode. In Figure 8, two devices are cascaded to generate  $3V_{in}$ . An example of using the circuit in Figure 7 or Figure 8 is generating  $+15V$  or  $-15V$  from a  $+5V$  input. Note that the number of  $n$  is practically limited since the increasing of  $n$  significantly reduces the efficiency and increases the output resistance and output voltage ripple.

#### REGULATING $V_{out}$

It is possible to regulate the output of the MAX660 by use of a low dropout regulator (such as LP2951). The whole converter is depicted in Figure 9. This converter can give a regulated output from  $-1.5V$  to  $-5.5V$  by choosing the proper resistor ratio:

$$V_{out} = V_{ref} \left( 1 + \frac{R_1}{R_2} \right)$$

where  $V_{ref} = 1.235V$ .

**Other Applications** (Continued)**OTHER SWITCHED-CAPACITOR CONVERTERS**
