MOS INTEGRATED CIRCUIT $\mu$ PD70108

## V20 ${ }^{\text {TM }}$ 16-/8-BIT MICROPROCESSOR

The $\mu$ PD70108 (V20) is a CMOS 16 -/8-bit microprocessor. It has a 16 -bit architecture and is equipped with a 8-bit data bus. The $\mu$ PD 70108 has a powerful instruction set which includes bit processing and packed BCD operation and high speed multiplication/division instructions, etc. and contains an 8080 emulation function. Further, the $\mu$ PD70108 contains a standby function which can greatly lower its power consumption. The $\mu$ PD70108 is software compatible with the 16 -bit microprocessor $\mu$ PD70116 (V30 ${ }^{\text {rM }}$ ).

Its functions are described in details in the manual indicated below. Please read this manual before starting design.

- V20, V30 User's Manual Hardware: IEM-871
- 16-bit V Series User's Manual Instruction: IEU-804

## FEATURES

- Memory addressing space: 1 M bytes
- Minimum instruction execution time:
: 400 ns ( $5 \mathrm{MHz}, 5 \mathrm{~V}$; 70108-5) 250 ns ( $8 \mathrm{MHz}, 5 \mathrm{~V} ; 70108-8$ ) 200 ns ( $10 \mathrm{MHz}, 5 \mathrm{~V}$; 70108-10)
- High-speed multiplication/division instruction:
: 3.8 to $11.4 \mu \mathrm{~s}$ ( $5 \mathrm{MHz}, 5 \mathrm{~V}$; 70108-5)
2.4 to $7.1 \mu \mathrm{~s}$ ( $8 \mathrm{MHz}, 5 \mathrm{~V}$; 70108-8) 1.9 to $5.7 \mu \mathrm{~s}$ ( $10 \mathrm{MHz}, 5 \mathrm{~V}$; 70108-10)
- High-speed block transfer instruction: : 625 K words/second ( $5 \mathrm{MHz}, 5 \mathrm{~V}$; 70108-5)

1 M words/second ( $8 \mathrm{MHz}, 5 \mathrm{~V}$; 70108-8)
1.25 M words/second ( $10 \mathrm{MHz}, 5 \mathrm{~V}$; 70108-10)

- Following microprocessors are offered as a dedicated clock pulse generator/driver.
- $\mu$ PD7 $1084 \quad$ : for $\mu$ PD70108-5 and -8
- $\mu$ PD71011 $:$ for $\mu$ PD70108-5 and -8
- $\mu$ PD71011-10 : for $\mu$ PD70108-10

## 1. PIN FUNCTIONS

There are some pins which work for either a small system or a large system, and others for both small and large systems.
(1) A15 to A8 (Address Bus) ... small/large

These pins output the middle 8 bits of the 20-bit address information. They are 3 -state outputs and become high-impedance during hold-acknowledge.
(2) AD7 to ADO (Address/Date Bus) ... small/large

These are buses for both address and data. They output the lower 8 bits of 20-bit address information and input/output data using the time-division method.
The 16-bit data input/output is divided into two times. The 1st byte is lower and the $\mathbf{2 n d}$ byte is higher.
These pins are 3-state inputs/outputs and they become high-impedance during hold-acknowledge and interruption.
(3) NMI (Non-Mackable Interrupt) ... small/large

This is an interrupt request input which is non-maskable by software.
This input is active at the rising edge, and it can be detected at any clock cycle. The actual interrupt servicing begins after the completion of executing instruction.
Interrupt start address for the above interrupt is decided by the interrupt vector 2.
After the rising edge, NMI signal must be kept at the high level of the minimum 5 clock cycles. Its priority is shown below. Hold request can be accepted during the NMI acknowledge.

$$
\text { INT < NMI < HLDRQ (small) or } \overline{\mathrm{RO}} \text { (large) }
$$

This interrupt can be used for the release of a standby mode.
(4) INT (Maskable Interrupt) ... small/large

This is an interrupt request input which is maskable by software.
This input is active at the high level and can be detected at the last clock cycle of an instruction, then accepted if this input is interrupt enable status (if interrupt enable flag IE is set). The external device checks if the INT interrupt request has been accepted or not by $\overline{\operatorname{INTAK}}$ signal output from the CPU.
INT signal must be kept at a high level until the first $\overline{\text { INTAK }}$ signal is output.
The priority is shown below. If a NMI arises simultaneously, the NMI takes priority over the INT. Hold request can be accepted during the INT acknowledge.

$$
\text { INT < NMI < HLDRQ (small) or } \overline{\operatorname{RO}} \text { (large) }
$$

This interrupt can be used for the release of a standby mode.
(5) CLK (Clock) ... small/large

This is an external clock input.

## （6）RESET（Reset）．．．small／large

This is a CPU reset input which is active at the high level．It takes priority over all operations．
After RESET is released，the CPU starts a program from FFFFOH．
RESET input is used not only for usual CPU start，but also for the release of a standby mode．
（7）READY（Ready）．．．mmall／large
When memory or I／O cannot end the read／write operation within the basic access time of the CPU， this signal is requested to be inactivated（at the low level）to generate wait state（TW）in the CPU， and to extend the read／write cycle．
If the READY signal is active（at the high level）at T3 or TW state，the CPU won＇t generate any wait state．
Since this signal cannot guarantee correct operation unless it satisfies setup／hold time，it should be synchronized with an external device．
（8）$\overline{\text { POLL }}$（Poll）．．．small／large
$\overline{\text { POLL input is checked by a POLL instruction．If the signal is at the low level，the next instruction }}$ is executed．If it is at the high level，$\overline{\text { POLL }}$ input is checked every 5 －clock eycle which continues until the signal is at the low level．
These functions are utilized to synchronize the CPU＇s program with external device operations．
（9）INTAK（Interrupt Acknowledgel ．．．small
This pin outputs when it receives INT signal．An external device inputs the interrupt vector in synchronization with this signal to the CPU through data buses（AD7 to AD0）．
This output is fixed at the high level in a standby mode．
（10）ASTB（Addrese Strobe）．．．small
This is a strobe signal which is output to latch address information into an external latch．
Once this output gets at the high level（for about $1 / 2$ clock）in a standby mode，then it is fixed at the low level．
（11）BUFEN（Buffer Enable）．．．small
This is a signal used as an output enable signal of external bi－directional buffers．It is output when data is exchanged with memory or $1 / O$ ，or an interrupt vector is input．
This output is fixed at the high level in a standby mode．
This pin is a 3－state output，its impedance is high during the hold acknowledge．

## （12）BUF $\bar{R} / W$（Buffer Read／Write）．．．small

This signal is output to decide the data transfer direction of external bi－directional buffers．It shows the sending direction from the CPU to an external device at a high level，and the receiving direction from an external device to the CPU at the low level．
This output is fixed at the high or low level in a standby mode．
This pin is a 3 －state output，its impedance is high during the hold acknowledge．
（13） $10 / \bar{M}$（10／Memory）．．．small
The signal is output to differentiate I／O access from memory access．It shows the I／O at the high level，and memory at the low level．
This output is fixed at the high or low level in a standby mode．
This pin is a 3－state output，its impedance is high during the hold acknowledge．
(14) WR (Write Strobe) ... small

The signal is output when data is written to I/O or memory, the distinction between I/O and memory is executed by the $10 / \bar{M}$ signal.
This output is fixed at the high level in a standby mode.
This pin is a 3-state output, its impedance is high during the hold acknowledge.
(15) HLDAK (Hold Acknowledge) ... small

An acknowledge signal is output, which shows that the CPU received a hold request signal (HLDRQ).
While this signal is active (at the high level), address bus, address/data bus, and control bus of 3state output is high-impedance.
(16) HLDRQ (Hold Request) ... small

A signal is input, which allows an external device to request the CPU to release address bus, address/data bus, and control bus.
Since this signal cannot guarantee correct operation unless it satisfies setup time, it should be synchronized with external device.
(17) $\overline{\mathrm{RD}}$ (Read Strobe) ... small/large

This signal is output when reading data from I/O or memory. The distinction between the $1 / O$ and the memory is executed by the $10 / \bar{M}$.
This signal exists originally for a small mode, but it may be output at the same timing in a large mode.
This output is fixed at the high level in a standby mode.
This pin is a 3-state output, its impedance is high during the hold acknowledge.
(18) S/LG (Small/Large) ... small/large

This is a pin to decide the CPU operation mode. This pin is used fixed at the high or low level. This pin operates at the high level in a small mode, and at the low level in a large mode.
The pin numbers indicated differentiate their functions depending on the mode to be operated, then each pin has its own name.

| Pin NumberNato |  |  | Function |  |
| :---: | :---: | :---: | :---: | :---: |
| DIP | QFP | QFJ | $\mathbf{S} / \overline{\mathrm{LG}}=\mathrm{High}$ | $\mathbf{S} / \overline{\mathbf{L G}}=$ Low |
| 24 | 38 | 27 | INTAK | QS1 |
| 25 | 39 | 28 | ASTB | Oso |
| 26 | 41 | 29 | $\overline{\text { BUFEN }}$ | BSO |
| 27 | 42 | 30 | BUF $\overline{\mathrm{R}} / \mathrm{W}$ | BS1 |
| 28 | 43 | 31 | $10 / \bar{M}$ | BS2 |
| 29 | 44 | 32 | $\overline{W R}$ | BUSLOCK |
| 30 | 45 | 33 | HLDAK | $\overline{\mathrm{RQ}} / \overline{\mathrm{AK} 1}$ |
| 31 | 47 | 34 | HLDRQ | $\overline{\mathrm{RQ}} / \overline{\mathrm{AKO}}$ |
| 34 | 50 | 37 | LBSO | Always high |

Note Pin number is different from package.
(19) LBSO (Latched Bus Status 0) ... small

This signal is used with the $I O / \bar{M}$ signal and BUF $\bar{R} W$ signal and informs external what the current bus cycle is.

| $10 / \bar{M}$ | BUF $\bar{R} W$ | LBSO | Bus cycle |
| :---: | :---: | :---: | :--- |
| 0 | 0 | 0 | Program fetch |
|  |  | 1 | Memory read |
|  | 1 | 0 | Memory write |
|  |  | 1 | Receiving state |
| 1 | 0 | 0 | Interruption acknowledge |
|  |  | 1 | I/O read |
|  | 1 | 0 | I/O write |
|  |  | 1 | Hold |

(20) A19/PS3 to A16/PS0 (Address Bus/Processor Status) ... small/large

This is a dual-function output pin for address bus and processor status signal, the contents of each pin are output by time multiplexing.
As an address bus, the upper 4 bits are output out of the $\mathbf{2 0}$-bit memory address. 0 is output to all bits during the $1 / O$ access.
Processor status signal is output to both memory and I/O accesses. PS3 is always 0 in native mode, and always 1 in an emulation mode. The contents of interrupt enable flag (IE) is output to PS2. PS1 or PS0 shows which segment is currently used.

| A17/PS 1 | A16/PS0 | Segment |
| :---: | :---: | :--- |
| 0 | 0 | Data segment 1 |
| 0 | 1 | Stack segment |
| 1 | 0 | Program segment |
| 1 | 1 | Data segment 0 |

These outputs are fixed at the high or low level in a standby mode.
The A19/PS3 to A16/PS0 pins are 3-state outputs and impedance is high during the hold acknowledge.
QS1, OSO (Queue Status) ... large
This signal notifies an external device (floating-point operation coprocessor) of the instruction queue status in the CPU.

| OS1 | OSO | Status of Instruction Queue |
| :---: | :---: | :--- |
| 0 | 0 | No operation (no change in the queue) |
| 0 | 1 | First byte of instructions |
| 1 | 0 | Empty |
| 1 | 1 | After 2nd byte of instructions |

This status of instruction queue represents the status when EXU accesses an instruction queue． The contents which are output to the OS1 and OSO pins are effective only in the $\mathbf{1}$ clock cycle immediately after this queue access．
This status signal is offered so that the coprocessor for floating－point operation can monitor the CPU program execution state and process when the control is shifted to the coprocessor itself（by FPO：Floating－Point Operation instruction）．
These outputs are fixed at the low level in standby mode．
（22）BS2 to BS0（Bus Status）．．．large
This is a status signal to inform an external bus controller what the current bus cycle is．
The external bus controller decodes these signals，and generates control signals to access memory or I／O．

| BS2 | BS1 | BSO | Bus Cycles |
| :---: | :---: | :---: | :--- |
| 0 | 0 | 0 | Interrupt acknowledge |
|  |  | 1 | I／O read |
|  | 1 | 0 | I／O write |
|  |  | 1 | Halt |
| 1 | 0 | 0 | Program fetch |
|  |  | 1 | Memory read |
|  | 1 | 0 | Memory write |

These outputs are fixed at the high level in a standby mode．
These pins are 3－state outputs，and impedance is high during the hold acknowledge．
These signals become high when the clock rises immediately after RESET is activated and remain high until the next rise of the clock．After this 1 clock cycle，the signals become high－impedance．
（23）BUSLOCK（Bus Lock）．．．large
This is the signal to request the other master CPUs in a multiprocessor system not to use system bus，when 1 instruction following the BUSLOCK front end instruction is being executed．
This output is fixed at the high level in a standby mode thowever，it is fixed at the low level if BUSLOCK instruction exists before HALT instruction）．
This pin is a 3－state output and impedance is high during the hold acknowledge．
（24）$\overline{\mathrm{RQ}} / \overline{\mathrm{AK1}}, \overline{\mathrm{RQ}} / \overline{\mathrm{AKO}}$（Hold Request／Acknowledge）．．．large
$\overline{R Q} / \overline{A K I}$ and $R \mathbb{A K O}$ are common pins for both bus hold request input（RO）and bus hold acknowledge signal output（AK）．Their priority is as follows：

$$
\overline{R Q} / \overline{A K 1}<\overline{R Q} / \overline{A K O}
$$

These pins are 3－state inputs／outputs．They incorporate a pull－up resistor and are set inactive（at the high level）in the open（float）status．
When this signal is used as a bus hold request input（ $\overline{\mathrm{RQ}}$ ），it cannot guarantee correct operation unless it satisfies setup／hold time．Therefore，it should be synchronized with an external device．
（25）Voo（Power Supply）．．．small／large
This is a positive power supply pin．
（26）GND（Ground）．．．small／large This is a GND potential．
（27）．IC（Internally Connected）
Set this to a GND potential．

## 2．REGISTER CONFIGURATION

## 2．1 PFP（Profotch Pointer）

Prefetch pointer is a 16－bit binary counter holding offset information of the program memory address which BCU is to prefetch to an instruction queue．

The PFP is incremented every time BCU prefetches instruction bytes from a program memory．Also， a new location is loaded when branch，call，return，or break instruction is executed．The contents of PFP at this point are same as that of the PC（Program Counter）．

PFP is always used together with PS（Program Segment）register．

## 2．2 Q0 to 03 （Prefetch Queue）

The $\mu$ PD70108 has a 4－byte instruction queue（FIFO）．It can store the maximum instruction code of 4 bytes which BCU prefetches．

The instruction codes stored in the queue are fetched and executed by EXU．
When branch，call，return，or break instruction is executed，or external interrupt is processed，the queue contents are cleared，and an instruction of a new location is prefetched．

Usually，the $\mu$ PD 70108 executes prefetch if the queue has blank of 1 byte or more．
If the average execution time of several sequential instructions exceeds the number of clocks，to some extent，which is necessary for prefetching the instruction codes of each instruction，and when EXU ends the execution of one instruction，then the instruction codes which EXU can execute consecutively will be ready in a queue，and the fetch time from external memory may be deducted from the instruction execution time．Therefore，it is possible to increase the processing speed compared with the CPU which fetches and executes in each instruction．

The effect of queue will be reduced，in inverse proportion to the number of instructions whose queue is cleared like the above－mentioned execution of branch instruction，or if the instructions with short execution time continue．

## 2．3 DP（Data Pointer）

Data pointer is a 16 －bit register which specifies the address for reading／writing variables．
The contents of register including the offset of the effective and memory addresses which are created in EA generator are transferred to this data pointer．

## 2．4 TEMP（Temporary Communication Register）

This is a 16 －bit temporary communication register between an external data bus and EXU．
For the purpose of byte access，TEMP can read／write upper and lower bytes independently．
Basically，EXU terminates write operations by transferring data to TEMP，then confirms the data transfers from an external bus to TEMP and terminates read operations．

### 2.5 Segment Register (PS, SS, DSO, DS1)

In the $\mu$ PD70108, memory address is divided into logical segments by the 64 K bytes, the start address of each segment is specified by a segment register, the offset after the start address is specified either by another register or an effective address.

There are four types of segment registers:

| Segment Register | Default Offset |
| :--- | :--- |
| PS (Program Segment) | PFP |
| SS (Stack Segment) | SP, effective address |
| DS0 (Data Segment 0) | IX, effective address |
| DS1 (Data Segment 1) | IY |

A pair of PS and PFP (Prefetch Pointer) and that of DS1 and IY are fixed.
SS is paired with SP in normal stack operation, but it offsets effective address when BP register is selected as a base register.

DSO is used together with IX in a block transfer processing, but it offsets effective address in the other processing.

In the addressing which defines SS as a segment register when using BP register as a base register, it is possible to use the other 3 types of segment registers for a segment selection by using segment overlaid prefix instruction (PS:, DS0:, DS1:).

### 2.6 ADM (Address Modifier)

ADM (Address Modifier) performs the generation of physical address (addition of segment register to PFP or DP) and the increments of PFP (Prefetch Pointer).

### 2.7 General Registers (AW, BW, CW, DW)

There are four different types of $\mathbf{1 6}$-bit general registers. It is possible to access as an 8-bit register (AH, $\mathrm{AL}, \mathrm{BH}, \mathrm{BL}, \mathrm{CH}, \mathrm{CL}, \mathrm{DH}$, and DL) by dividing each register into the upper and lower 8 bits.

Therefore, these registers can be used as an 8 -bit or $\mathbf{1 6 - b i t}$ register for a variety of instructions, such as transfer instructions, arithmetic operation instructions, and logical operation instructions.

Also, the following list shows that the each register can be used as a default register for a specific instruction processing.

AW : Word multiplication/division, word I/O, data conversion
AL : Byte multiplication/division, byte I/O, BCD rotate, data conversion, translation
AH : Byte multiplication/division
BW : Translation
CW : Loop control branch, repeat prefix
CL : Shift instruction, rotate instruction, BCD operation
DW : Word multiplication/division, indirect addressing I/O

### 2.8 Pointer (SP, BPI and Index Register (IX, IY)

These are used as a base pointer or an index register during the memory access executed by based addressing, indexed addressing, and based/indexed addressing.

Like a general register, they can be used for instructions, such as transfers, arithmetic operations, and logical operations, but they cannot be used as an 8-bit register for the same instructions.

The following list shows that each register can be used as a default register for the purpose of a specific processing.

SP : Stack manipulation
IX : Block transfer (on the source side), BCD string operation
IY : Block transfer (on the destination side), BCD string operation

### 2.9 TA/TB (Temporary Register/Shifter A/B)

TATB are 16-bit temporary registers/shifters which are used for multiplication/division and shift/rotate (including BCD rotate) instructions.

TA and TB work as a 32-bit temporary register/shifter when executing the multiplication/division instructions, while only TB works as a 16 -bit temporary register/shifter when executing the shift/rotate instructions.

Both TA and TB can read/write the upper and lower byte independently between the internal buses.
TATB are inputs of ALU.

### 2.10 TC (Temporary Register C)

TC is a 16-bit temporary register which is used for the internal processing, such as multiplication/ division, etc.

TC is an input of ALU.

### 2.11 ALU (Arithmotic \& Logic Unit)

ALU (Arithmetic \& Logic Unit) consists of a full adder and a logic unit, and it performs the arithmetic operations \{addition/subtraction/multiplication/division, increment, decrement, and complement operations) and the logical operations (test, AND, OR, and XOR, and the bit-wise test, set, clear, and inversion).

### 2.12 PSW (Program Status Word)

Program status word consists of the 6 types of status flags and the 4 types of control flags.

## Status flags

- V (Overflow)
- $\mathbf{S}$ (Sign)
- Z (Zero)
- AC (Auxiliary Carry)
- P (Parity)
- CY (Carry)

## Control flags

- MD (Mode)
- DIR (Direction)
- IE (Interrupt Enable)
- BRK (Break)

These flags are stack processed by manipulating the following word images.

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\begin{gathered} M \\ D \end{gathered}$ | 1 | 1 | 1 | V | D 1 $R$ | $\stackrel{1}{E}$ | B R K | S | Z | 0 | $\stackrel{A}{C}$ | 0 | P | 1 | $\stackrel{C}{\text { Y }}$ |

Status flags are automatically set and reset according to the execution result (data value) of each instruction.

CY flag can be set, reset, or inverted directly by instructions.
Control flags are set or reset by instructions, then control the CPU operations.
MD flag is reloadable only between the execution of BRKEM instruction and that of RETEM instruction, it may not be restored in other places even if RETI, or POP PSW instruction is executed.

### 2.13 LC (Loop Counter)

LC (Loop Counter) is a 16-bit register which counts the number of loops of the primitive block transfer/ I/O instructions (MOVBK, OUTM, etc.) controlled by repeat prefix instructions (REP, REPC, etc.), and the number of shifts of multi-bit shift/rotate instructions.

### 2.14 PC (Program Counter)

The program counter is a 16-bit binary counter which holds the offset information of the program memory address which the EXU is currently to execute.

The PC is incremented each time a microprogram fetches an instruction byte out of an instruction queue. Also, a new location is loaded when branch, call, return, or break instruction is executed. The contents of the PC at this point are same as the PFP (Prefetch Pointer).

### 2.15 EAG (Effective Address Generator)

EAG (Effective Address Generator) is a circuit which performs high-speed effective address calculations needed during the memory access. It terminates the calculation by two clocks in all addressing modes.

If it reads the byte (the 2 nd or 3rd byte) specified by the instruction's operand and requires memory access, it will generate a control signal related to the ALU and the associated register operation, and will caiculate an effective address to transfer the signal to the DP (Data Pointer).

If necessary, it requests the BCU to activate a bus cycle (memory read).

### 2.16 Instruction Decoder

Instruction decoder classifies the 1st byte of an instruction code into the groups with a specific function, and holds it during the execution of microinstruction.

### 2.17 Microaddress Register

Microaddress register specifies the address of microinstruction ROM which should be executed consecutively.

When starting the exacution of microinstructions, the 1st byte of instructions stored in a queue as a start address is read into this register, and the register specifies the start address of the specific microinstruction sequence.

### 2.18 Mieroinstruction ROM

Microinstruction ROM holds 29-bit width of microinstructions for 1024 words.

### 2.19 Microinstruction Sequence Circuit

This circuit manages the control of a microaddress register, the output control of a microinstruction ROM, and synchronization of the EXU and BCU.

## 3．HIGH SPEED EXECUTION OF INSTRUCTIONS

In order to reduce the instruction execution time，the $\mu$ PD70108 is equipped with the following hardware features．
－EXU internal dual data bus
－Effective address generator
－16－／32－bit temporary register／shifter（TA，TB）
－16－bit loop counter（LC）
－PC（Program Counter）and PFP（Prefetch Pointer）

## 3．1 Dual Data Bus Method

In order to reduce the number of processing steps required for executing instructions，the dual data bus method of main data bus（16－bit）and sub data bus（16－bit）is adopted．This method realizes roughly $30 \%$ reduction of processing time（compared with a single bus method）in addition／subtraction，logical operations，and compare instructions．

Example $\mathrm{ADD} \mathrm{AW}, \mathrm{BW} ; \mathrm{AW} \leftarrow \mathrm{AW}+\mathrm{BW}$

|  | Single bus | Dual bus |
| :--- | :--- | :--- |
| Step 1 | ALU $\leftarrow A W$ | $A L U \leftarrow A W, B W$ |
| 2 | $A L U \leftarrow B W$ | $A W \leftarrow A L U$ |
| 3 | $A W \leftarrow A L U$ |  |

### 3.2 Effective Address Generator

This is a circuit which may perform high-speed processing of effective address calculation required during the memory access.

This dedicated hardware has realized the high-speed processing which is several times faster than the microprogram method. It requires just 2 clocks for effective address calculations in all addressing modes, while the microprogram method requires 5 to $\mathbf{1 2}$ clocks for the calculation.

3.3 16-/32-Bit Temporary Register/Shifter (TA, TB)

Temporary register/shifter (TA, TB) is offered for multiplication/division and shift/rotate instructions.
The adoption of this circuit has increased the speed of multiplication/division instructions particularly. This speed is 4 times as fast as that of the microprogram method.

TA + TB : 32-bit temporary register/shifter for multiplication/division instructions
TB : 16-bit temporary register/shifter for shift/rotate instructions

### 3.4 Loop Counter (LC)

This counts the number of loops of primitive block transfer/l/O instruction which is controlled by repeat prefix instruction, and the number of shifts of multi-bit shift/rotate instruction.

For example, the multi-bit rotate of register is executed as follows. It has increased the speed up to two times that of microprogram method.

RORC AW, CL: CL $=5$

| Microprogram method | LC method |
| ---: | :--- |
| $8+4 \times 5=28$ clocks | $7+5=12$ clocks |

### 3.5 PC and PFP

The hardware contains both a prefetch pointer (PFP) which addresses program memory prefetching, and a program counter (PC) which addresses program memory which is going to be executed. Because of this, the instruction execution time for branch, call return, and break instructions has been reduced for another few clocks, compared with a microprocessor with one PFP.

## 4. DESCRIPTION OF CHARACTERISTIC INSTRUCTIONS

### 4.1 Variable Length Bit Field Operation Instructions

There are two types of instructions, INS (Insert Bit Field) and EXT (Extract Bit Field). These instructions are very effective for a computer plotting and a high-level language. For example, they may be applied to a packed array of Pascal and a record-type data structure.
(1) INS reg8, reg8'/INS reg8, imm4

This instruction transfers the lower bit data (out of the 16-bit data of AW register) which has a length specified by the 2nd operand, to memory area which is decided by a byte offset which is addressed by a segment register DS1 and a indexed register IY, and a bit offset which is specified by the values (0 to 15) of the 1st operand.
After the completion of transfer, the register which is specified by both IY register and the 1 st operand is automatically updated to show the next bit field.
The effective values of the 2 nd operand are 0 to 15 (1-bit length at 0,16 -bit length at 15 ) only.

Bit field data can extend over the byte boundaries of memory.
(2) EXT reg8, reg8'/EXT reg8, imm4

This loads a bit field data with a bit length defined by the 2nd operand, from the memory area decided by the bit offset apecified by a byte offset which is addressed by a segment register DSO and an index register IX and a bit offset which is specified by the values ( 0 to 15) of the ist operand, to the AW register.
After the completion of transfer, the register which is specified by both IX register and the 1st operand is automatically updated to show the next bit field.
The effective values of the 2 nd operand are 0 to 15 (1-bit length at 0,16 -bit length at 15 ) only.

Bit field data can extend over the byte boundaries of memory.

### 4.2 Packed BCD Operation Instructiona

The instructions consist of ADD4S, SUB4S, and CMP4S which may process packed BCD in a string form, and ROR4 and ROL4 which process it as a byte/word operand.
(1) ADD4S

This instruction sums a packed BCD string addressed by an index register $I X$ and that by a index register IY, and stores the result to a string which is addressed by IY. The string length (number of BCD digits) is decided by a CL register. The operation result affects both a zero flag $(Z)$ and a carry flag (CY).

$$
B C D \text { string }(I Y, C L) \leftarrow B C D \text { string }(I Y, C L)+B C D \text { string }(I X, C L)
$$

(2) SUB4S

This instruction subtracts a packed BCD string addressed by an index register $\mathbb{X}$ from that by an index register IY, and stores the result to a string addressed by IY. The string length (number of $B C D$ digits) is decided by a CL register. The operation result affects both a zero flag ( $Z$ ) and a carry flag (CY).

$$
\text { BCD string (IY, CL) } \leftarrow B C D \text { string (IY, CL) - BCD string (IX, CL) }
$$

(3) CMP4S

This instruction performs the same subtraction as SUB4S does, but it does not store the result, and only affects a zero flag ( $Z$ ) and a carry flag (CY).
$B C D$ string (IY, $C L$ ) - $B C D$ string ( $(X, C L$ )
(4) ROL4

This instruction handles either a register which is directly addressed by an instruction byte or byte data of memory as BCD data, then rotates its one digit to the left through the lower 4 bits (ALL) of an AL register.

(5) ROR4

This instruction handles either a register which is directly addressed by an instruction byte or byte data of memory as BCD data, then rotates its one digit to the right through the lower 4 bits (ALL) of an AL register.

### 4.3 Stack Operation Instructions

(1) PREPARE imm 16, imms

This instruction is used to create a "Stack Frame" which is necessary for a block-structured highlevel language (e.g. Pascal, Ada, etc.). A stack frame contains both a pointer group pointing a frame of variables which may be referred from the procedures and the area of local variables.
Description is continued below using an example program made by a Pascal type language.

```
program EXAMPLE;
    procedure \(P\);
        var \(a, b, c\), ;
        procedure \(Q\);
            var d,e;
            procedure \(R\);
                var f,g;
                begin
                        \(d:=a+f+g ;\)
            end:
            begin
                R;
                \(b:=d+e ;\)
            end:
        begin
            \(a:=b+c ;\)
            Q;
        end:
(*main program*)
    begin
            P;
    end.
```

Remark A word is used for all variables.

This is a program example in which 3-layered procedure blocks are nesting. Procedure $P$ defines variables $a, b$, and $c$, procedure $Q$ defines $d$ and $e$, and procedure $R$ defines $f$ and $g$. Therefore, global variables $a, b$, and $c$, are referred from procedure $Q$, and variables. $a, b, c, d$, and e from procedure R.
The PREPARE instruction copies a frame pointer to reserve the area of local variables and to enable the reference to global variables. The 1st operand specifies an area size (byte unit) to be reserved for local variables, and the 2 nd operand shows the depth of the procedure block the depth is called "lexical level").
The frame's base address which is created by the PREPARE instruction is set to a base pointer BP. After having compiled the EXAMPLE program, this program converts itself to a program listed in the next page (The DISPOSE instruction which is used in an assembler program returns the state of both a stack pointer SP and a base pointer BP to the state immediately before the PREPARE instruction is executed. Please refer to (2)).

| START: | MOV | SP, SPTOP |
| :---: | :---: | :---: |
|  | MOV | BP , SP ; (1) |
|  | CALL | P ; (2) |
|  | BR | SYSTEM |
| P : | PREPARE | 6, 1 ; (3) |
|  | MOV | AW, [BP] [B+BLEVEL * 2 ] |
|  | ADD | AW, [BP][C+CLEVEL*2] |
|  | MOV | [BP] [A+ALEVEL*2], AW |
|  | CALL | Q |
|  | DISPOSE |  |
|  | RET |  |
| Q: | PREPARE | 4,2 ; (4) |
|  | CALL | R |
|  | MOV | AW, [BP] [D+DLEVEL*2] |
|  | ADD | AW, [BP] [E+ELEVEL*2] |
|  | MOV | IY, [BP][BLEVEL*2] |
|  | MOV | SS: [IY][B+BLEVEL*2], AW |
|  | DISPOSE |  |
|  | RET |  |
| $\mathrm{R}:$ | PREPARE | 4, 3 ; (5) |
|  | MOV | AW, [BP][F+FLEVEL*2] |
|  | ADD | AW, [BP][G+GLEVEL*2] |
|  | MOV | IY, [BP][ALEVEL*2] |
|  | ADD | AW, SS:[IY] [A+ALEVEL*2] |
|  | MOV | IY, [BP][DLEVEL*2] |
|  | MOV | SS: [IY] [D+DLEVEL*2], AW |
|  | DISPOSE |  |
|  | RET |  |
| ; A |  | ALEVEL $=-1$ |
| ; B |  | BLEVEL $=-1$ |
| ; C | -6 | CLEVEL $=-1$ |
| ; D | -2 | DLEVEL $=-2$ |
| ; E | -4 | ELEVEL $=-2$ |
| ; $\mathbf{F}$ | -2 | FLEVEL $=-3$ |
| ; G | -4 | GLEVEL $=-3$ |

The process in which a stack frame is created as the program runs is illustrated in the following pages. Numbers correspond to those placed in the program's comment list.

The PREPARE instruction saves BP to a stack first in order to restore the BP of a procedure at the called side when the procedure finishes. Then, it pushes a frame pointer (a saved BP) onto the stack within the range accessible from the called procedure. The accessible range equals to the value which is subtracted by one from the lexical level of the procedure.
If the lexical level is one or more, the instruction pushes its own frame point onto the stack. This is done to copy a frame pointer of the called procedure, when the instruction copies a frame pointer in the other procedure which was called from this procedure.
Then, the instruction sets the value of new frame pointer to BP, and reserve the area of the local variables to be used in the procedure, onto the stack. I.e. it subtracts the value worthy of local variables from SP.

```
    display = 2nd operand
    dynamics = 1st operand
SP = SP-2;
(SP) = BP;
temp = SP;
if display > 0 then begin
    repeat display - 1 times
        begin
            SP = SP-2;
            BP = BP-2;
            (SP) = (BP);
        end;
    SP = SP-2;
    (SP) = temp;
    end;
BP = temp;
SP=SP-dynamics
```

## Data access

## （a）Access of local variables

Local variables are placed in the frame of the procedure itself．Therefore，the effective address EA．L of a local variable is calculated by the following formula．

$$
E A . L=S S:(B P+\text { offset })
$$

This＂offset＂is the sum of the offset values which are located from a frame size stacked onto the frame（the base value of an accessible frame）and the base value of local variable area，to that variable．

## （b）Access of global variables

Global variables are located in the address added by the offset value which accesses the target base pointer out of the old base pointers loaded onto the stack frame and attempts to access the value．
Therefore，the effective address EA．G of global variables is calculated by the following expression：

$$
E A . G=S S: \quad((S S:(B P+\text { offset } 1))+\text { offset } 2\rangle
$$

This offset 1 is the offset value from the base value（BP value）of the current frame to the address in which the base address of a frame（including the global variable to be referred）is stored． Also，the offset2 is the offset value from the base value of a frame which holds the variable to be referred to that variable．
（2）

## DISPOSE

This instruction releases one of the stack frames which is created by PREPARE instruction．For BP it loads a point value which points the previous frame，while for SP it loads a point value which points the least significant address of a frame．
$S P=B P ;$
$B P=(S P) ;$
$S P=S P+2$

### 4.4 Array Index Check Instructions

This is an instruction to check whether the index value to specify if an element exists in the defined area or not, in array-type data structure. If the index value exceeds the area, it activates BRK5.

The defined area value should be set to the 2 words (setting the lower bound value at the 1 st word, and the upper bound value at the 2 nd word) in the memory, before CHKIND instruction is executed. The index value is for the register (any $\mathbf{1 6}$-bit register) which an array manipulation program is using.

Memory

### 4.5 Mode Operation Instructions

The operating modes of the $\mu$ PD70108 consist of native mode (normal operation) and emulation mode (emulation operation of the $\mu$ PD8080AF instruction set). As a flag to switch these modes, a mode flag (MD) is provided in the bit 15 of PSW. The mode is changed to native mode when MD is 1 , and to emulation mode when MD is 0 . MD is set/reset directly or indirectly by the mode operation instruction.

The instructions to change modes from native to emulation are:

## BRKEM (Break for Emulation) RETI (Return from Interrupt)

The instructions to change modes from emulation to native are:

## RETEM (Return from Emulation)

CALLN (Call Native routine)

Also, either RESET input or external interrupt input (NMI, INT) turns emulation mode back to native mode.

(1) BRKEM imm 8

This is a basic instruction to activate emulation mode. This instruction saves PSW, PS, and PC, resets MD (0), and loads an interrupt vector specified by operand to PS and PC. This instruction neither affects interrupt enable flag (IE) nor breaks flag (BRK).
Fetching the instruction code of interrupt service routine (for emulation) which has jumped, the CPU interprets the code as an instruction of the $\mu$ PD8080AF and executes it.
The CPU interprets emulation mode as interrupt servicing.
In emulation mode, the register and flag actions of the $\mu$ PD8080AF are alternatively done by the register and flag of the $\mu$ PD70108 shown below.

| $\mu$ PD8080AF | $\mu$ PD70108 |
| :---: | :---: |
| $\mathbf{A}$ | $\mathbf{A L}$ |
| $\mathbf{B}$ | $\mathbf{C H}$ |
| $\mathbf{C}$ | $\mathbf{C L}$ |
| $\mathbf{D}$ | $\mathbf{D H}$ |
| $\mathbf{E}$ | DL |
| $\mathbf{H}$ | $\mathbf{B H}$ |
| $\mathbf{L}$ | $\mathbf{B L}$ |
| $\mathbf{S P}$ | $\mathbf{B P}$ |
| $\mathbf{P C}$ | PC |

| $\mu$ PD8080AF | $\mu$ PD70108 |
| :---: | :---: |
| $\mathbf{C}$ | $C Y$ |
| $Z$ | $Z$ |
| $S$ | $S$ |
| $P$ | $P$ |
| $A C$ | $A C$ |

Regarding stack operations, either SP in native mode or BP in emulation mode works as a stack pointer. Adoption of this independent stack pointer allows both modes to reserve independent stack area, and prevents them from destroying any stack in other mode by erroneous stack operation.
SP, IX, IY, and AH in native mode and the four segment register (PS, SS, DS0, and DS1) are not affected by emulation mode.
In emulation mode, the segment base of instruction is decided by the PS register (automatically decided by interrupt vector), and that of data by the DSO register (decided by a programmer just before entering emulation mode).
(2) RETEM (without operand)

When RETEM instruction is executed in emulation mode (this instruction is interpreted as an instruction of the $\mu$ PD8080AF), the CPU restores PS, PC, and PSW and returns to native mode, as if it returns from interrupt servicing. At this point, the contents (i.e. "1") in native mode which was saved in the stack by BRKEM instruction are restored, which sets the CPU to native mode.
(3) CALLN imm 8

When this instruction is executed in emulation mode (this instruction is interpreted as an instruction of the $\mu$ PD8080AF), the CPU save PS, PC, and PSW to the stack (MD $=0$ is saved), sets (1) a mode flag (MD), then loads the interrupt vector specified by operand to PS and PC. This instruction neither affects interrupt enable flag (IE) nor break flag (BRK).
Thus, interrupt routine in native mode can be called from emulation mode.
To return from this interrupt routine to emulation mode, RETI instruction should be executed.
(4) RETI (without operand)

This is a general instruction to return from an interrupt routine activated by BRK instruction or an external interrupt in native mode. If this instruction is executed at the end of an interrupt service routine activated by CALLN instruction in emulation mode, PS, PC, and PSW restoration is exactly the same as normal. Because the value ( $=0$ ) of mode flag (MD) in emulation mode is restored to MD if PSW is restored, the CPU is set to emulation mode, then further instructions are interpreted as an instruction of the $\mu$ PD8080AF and executed. RETI instruction is executed to return from an interrupt routine of native mode which was activated by NMI or INT interrupt request generated in emulation mode in the same way.

## 4．6 Floating－Point Operation Coprocessor Instruction

> FPO1 fp-op/FPO1 fp-op, mem FPO2 fp-op/FPO2 fp-op, mem

Thase are coprocessor＇s instructions for external floating－point operation．They leave operations to a coprocessor when the CPU fetches these instructions，then they only execute auxiliary processing （calculation of effective address，generation of physical address，and activation of memory read cycie）for a coprocessor if necessary．

When a coprocessor monitors these instructions，it interprets them as an instruction to itself and executes them．At this point，the coprocessor uses only the address information of memory read eycle only activated by the CPU，or both the address and read data，depending on a type of instruction．

FPO1 and FPO2 instructions have the same function，but different type of codes．
Also in the description of an actual assembler language，it is more common to use mnemonic to each instruction in a coprocessor，rather than to use the mnemonic，FPO1 or FPO2．

When the CPU fetches FPO1 or FPO2 and either of them requests memory access，it activates a memory read cycle．However，the data read by this should be used by a floating－point operation coprocessor，so it will never be handled by the CPU．

Also，the CPU activates a memory read cycle even if a floating－point operation coprocessor needs a memory write cycle，the data resulted from this activation is ignored as a dummy data，only memory address information is latched by a floating－point operation coprocessor．Then a floating－point operation coprocessor uses the address information to execute a memory write cycle．

## 5. INTERRUPT OPERATIONS

The $\mu$ PD70108 has mainly two types of interrupts; one by an external interrupt request, and the other by software processing.

They are classified further as follows:
(1) External interrupt
(a) NMI input (non-maskable)
(b) INT input (maskable)
(2) Software instruction
(a) Processing results of instruction

- Divide error by DIV or DIVU instruction
- Memory boundary over detection by CHKIND instruction
(b) Conditional break instruction
- When $V=1$ in BRKV instruction
(c) Unconditional break instruction
- 1-byte break instruction, BRK 3
- 2-byte break instruction, BRK imms
(d) Flag processing (single step)
- Sets BRK flag using stack operation
(e) Emulation-related instruction
- BRKEM imm8
- CALLN imm8

Any of the above interrupts should be selected by either automatically or sequentially specifying one point in the interrupt vector table which has been arranged beforehand, then decide interrupt routine start address.

Interrupt vector table is shown in the Figure 5－1．This table is assigned to the $1 K$－byte of the memory 000 H to 3 FFH ，and it may hold 256 vectors（using 4 bytes per vector）．

Figure 5－1．Interrupt Vector Table

The vectors 0 to 5 are specified by a use factor，and the vectors 6 to $\mathbf{3 1}$ are reserved．They are not available for a general use．

In the vectors 32 to 255，the 2－byte break instruction，BRKEM instruction，INT input，and CALLN instruction（during the emulation）are available for a general use．

One interrupt vector consists of 4 bytes． 2 bytes in the lower address is loaded to PC as an offset，while the other 2 bytes in the upper address is loaded to PS as a base．

## Example Vector 0

| 000 H | 001 H |
| :---: | :---: |
| 002 H | 003 H |

$$
\begin{aligned}
& \mathrm{PS} \leftarrow(003 \mathrm{H}, 002 \mathrm{H}) \\
& \mathrm{PC} \leftarrow(001 \mathrm{H}, 000 \mathrm{H})
\end{aligned}
$$

Based on this format, a programmer should initialize the contents of each vector to use at the beginning of a program.

The basic steps to jump in an interrupt service routine are listed as follows:

TA $\leftarrow$ vector lower (offset)
$T C \leftarrow$ vector upper (segment base)
$S P \leftarrow S P-2,(S P+1, S P) \leftarrow P S W$
$I E \leftarrow 0, B R K \leftarrow 0, M D \leftarrow 0$
$S P \leftarrow S P-2,(S P+1, S P) \leftarrow P S$
$P S \leftarrow T C$
$S P \leftarrow S P-2,(S P+1, S P) \leftarrow P C$
$P C \leftarrow T A$

## 6. STANDBY FUNCTIONS

$\mu$ PD70108 incorporates standby mode to decrease the power consumption while it is waiting for program's processing.

Standby mode is set by HALT instruction in native mode or HLT instruction in emulation mode.
In standby mode, internal clock is provided only for the circuit related to the function necessary for releasing the standby mode and the circuit related to bus hold control function, then no internal clock is provided for the other circuits. This may reduce the power consumption to a fraction of that for normal operation (native/emulation mode).

Standby mode is released by either RESET input or external interrupt inputs (NMI, INT).
Bus hold function is effective during the standby mode, however, it returns to standby mode when bus hold request is cleared.

## 7. I/O ADDRESS RESERVE

The upper 256 bytes (FFOOH to FFFFH) of $/ / O$ address might be used in the future. Do not use it at this time.

## 8. INSTRUCTION SET

Table 8-1. Legend of Operand Type

| Identifier | Description |
| :---: | :---: |
| reg | 8-/16-bit general register <br> (destination-side register in the instruction which uses two 8-/16-bit general registers) |
| reg' | Source-side register in the instruction which uses two 8-/16-bit general registers |
| reg8 | 8-bit general register |
|  | (destination-side register in the instruction which uses two 8-bit general registers) |
| reg8' | Source-side register in the instruction which uses two 8-bit general registers |
| reg16 | 16-bit general register |
|  | (destination-side register in the instruction which uses two 8-bit general registers) |
| reg $16{ }^{\circ}$ | Source-side register in the instruction which uses two 16-bit general registers |
| dmem | 8-/16-bit memory location |
| mem | 8-/16-bit memory location |
| mem8 | 8-bit memory location |
| mem16 | 16-bit memory location |
| mem32 | 32-bit memory location |
| imm | Constant in the range of 0 to FFFFH |
| imm3 | Constant in the range of 0 to 7 |
| imm4 | Constant in the range of 0 to FH |
| imm8 | Constant in the range of 0 to FFH |
| imm 16 | Constant in the range of 0 to FFFFH |
| acc | Register AW or AL |
| sreg | Segment register |
| src-table | Name of 256-byte conversion table |
| src-block | Name of a block which is addressed by register IX |
| dst-block | Name of a block which is addressed by register IY |
| near-proc | Procedure in the current program segment |
| far-proc | Procedure in the other program segment |
| near-label | Label in the current program segment |
| short-label | Label in the range, from the end of instruction to the -128 to +127-byte |
| far-label | Label in other program segment |
| memptr 16 | Word which includes the location's offset in the current program segment to which control attempts to move |
| memptr32 | Double word which includes the location's offset and segment base address in other program segment to which control attempts to move |
| regptr 16 | 16-bit general register which includes the location's offset in other program segment to which control attempts to move |
| pop-value | Number of bytes which are dumped from the stack (0 to 64K, usually even number) |
| fp-op | Immediate value to identify the instruction code of an external floating-point operation coprocessor |
| R | Register set |

Table 8-2. Legend of Operation Code

| Identifier | Description |
| :---: | :---: |
| W | Byte/word specification bit (0: byte, 1: word). |
|  | However, when $s$ is 1 , sign extended byte data is specified 16-bit operand even if $\mathbf{W}=1$. |
| reg | Register field (000 to 111) |
| reg' | Register field (000 to 111) (source-side register in the instruction which uses two registers) |
| mem | Memory field (000 to 111) |
| mod | Mode field (00 to 10) |
| 8 | Sign extension specification bit (0) sign is not extended, 1: sign is extended) |
| X,XXXX,YYY,ZZZ | Data to identify the instruction code of an external floating-point operation coprocessor. |

Table 8-3. Legend of Operation Description

| Identifier | Description |
| :---: | :---: |
| AW | Accumulator (16-bit) |
| AH | Accumulator (upper byte) |
| AL | Accumulator (lower byte) |
| BW | Register BW (16-bit) |
| CW | Register CW (16-bit) |
| CL | Register CW (lower byte) |
| DW | Register DW (16-bit) |
| BP | Base pointer (16-bit) |
| SP | Stack pointer (16-bit) |
| PC | Program counter (16-bit) |
| PSW | Program status word (16-bit) |
| IX | Index register (source) (16-bit) |
| IY | Index register (destination) (16-bit) |
| PS | Program segment register (16-bit) |
| SS | Stack segment register (16-bit) |
| DSo | Data segment 0 register (16-bit) |
| DS1 | Date segment 1 register (16-bit) |
| AC | Auxiliary carry flag |
| CY | Carry flag |
| P | Parity flag |
| S | Sign flag |
| Z | Zero flag |
| DIR | Direction flag |
| IE | Interrupt enable flag |
| $\checkmark$ | Overflow flag |
| BRK | Break flag |
| MD | Mode flag |
| (-.) | Contents of memory shown in the parentheses |
| disp | Displacement (8-/16-bit) |
| ext-disp 8 | 16-bit displacement which is sign-extended from 8-bit displacement |
| temp | Temporary register (8-116-/32-bit) |
| TA | Temporary register A (16-bit) |
| TB | Temporary register B (16-bit) |
| TC | Temporary register C (16-bit) |
| tmpey | Temporary carry flag (1-bit) |
| seg | Immediate segment register (16-bit) |
| offset | Immediate offset register (16-bit) |
| $\leftarrow$ | Transfer direction |
| + | Addition |
| - | Subtraction |
| $\times$ | Multiplication |
| + | Division |
| \% | Madula |
| $\wedge$ | AND |
| $v$ | OR |
| $\forall$ | Exclusive-OR |
| $x \times \mathrm{H}$ | Numeric value of 2-digit hexadecimal number |
| $\pm 00 \times \mathrm{H}$ | Numeric value of 4-digit hexadecimal number |

Table 8-4. Legend of Flag Operation

| Identifier | Description |
| :---: | :--- |
| (Blank) | No change |
| 0 | Cleared to 0 |
| 1 | Set to 1 |
| $\times$ | Set or cleared according to the result |
| U | Undefined |
| R | Pre-saved value is restored |

Table 8-5. Memory Addressing

| 11 | DS0 |

The instruction set is described in table form on the following pages.
The clock cycles indicated in the tables represent the time needed for the execution unit to execute instructions, and are based on the following conditions.

- The prefetch time and waiting time to use the bus are not included.
- Zero wait time is assumed for memory access. In other words, one bus cycle's clock cycle equals 4 clock cycles.
- Zero wait time is assumed for I/O access.
- Primitive block transfer instructions and primitive I/O instructions include the repeat prefix.

If the instruction performs both byte and word processing (holding W-bit), the value of the clock cycle is shown as follows:

The left side of / shows the clock cycle for the byte processing ( $\mathrm{W}=0$ );
The right side of / shows the clock cycle for the word processing ( $\mathrm{W}=1$ ).

For the clock cycles of block transfer-related instructions, refer to Table 8-8.

Table 8-8. Clock Cycles of Block Transfer-related Instructions:

| Instruction | Clock Cycles |  |
| :---: | :---: | :---: |
|  | Byte processing ( $W=0$ ) | Word processing ( $W=1$ ) |
| MOVBK | $11+8 / \text { rep }$ (11) | $\begin{gathered} \hline \text { 11+16/rep } \\ \text { (19) } \end{gathered}$ |
| CMPBK | $\begin{gathered} 7+14 / \text { rep } \\ \text { (13) } \end{gathered}$ | $\begin{gathered} 7+22 / \text { rep } \\ (21) \end{gathered}$ |
| CMPM | $7+10 / \text { rep }$ (7) | $\begin{gathered} 7+14 / \text { rep } \\ \text { (11) } \end{gathered}$ |
| LDM | 7+9/rep <br> (7) | $\begin{gathered} 7+13 / \mathrm{rep} \\ \text { (11) } \end{gathered}$ |
| STM | 7+4/rep <br> (7) | $\begin{gathered} 7+8 / \text { rep } \\ (11) \end{gathered}$ |
| INM | 9+8/rep <br> (10) | 9+16/гер (18) |
| OUTM | 9+8/rep <br> (10) | $\begin{gathered} 9+16 / \text { rep } \\ \text { (18) } \end{gathered}$ |

Remark Numeric values in parentheses are for single processing.

## 9. ELECTRICAL SPECIFICATIONS

## Absolute Maximum Rating (T: $=25^{\circ} \mathrm{C}$ )

| Parameter | Symbol | Conditions | Rating | Unit |
| :---: | :---: | :---: | :---: | :---: |
| Power supply voltage | Vod |  | -0.5 to +7.0 | V |
| Input voltage | $V_{1}$ | $\mathrm{VDD}=5 \mathrm{~V} \pm 10 \%$ | -0.5 to VDD +0.3 | $V$ |
| CLK input voltage | $V k$ |  | -0.5 to VDo +1.0 | $V$ |
| Output voitage | Vo |  | -0.5 to VDD +0.3 | V |
| Operating ambient temperature | Topt |  | -40 to +85 | ${ }^{\circ} \mathrm{C}$ |
| Storage temperature | Toto |  | -65 to +150 | ${ }^{\circ} \mathrm{C}$ |

Cautions 1. Do not connect output (and bidirectional) pins each other. Do not connect output (or bidirectionall pins directly to the Vdd, Vcc, or GND line. However, open drain pin and opan collector pins can be directly connected to Vod, Vec, or GND line. If timing design is made so that so signal conflict occurs, three-state pins can also be connected directly to three-state pins of external circuit.
2. Exposure to Absolute Maximum Ratings for extended periods may affect device reliability; exceeding the ratings could cause permanent damage. The parameters apply independently. The device should be operated within the limits specified under DC and AC Characteristics.

| Parameter | Symbol | Conditions |  | MIN. | TYP. | MAX. | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Input voltage, high | $V_{1 H}$ |  |  | 2.2 |  | Vod+0.3 | $V$ |
| Input voltage, low | Vil |  |  | -0.5 |  | 0.8 | $V$ |
| CLK input voltage, high | VKH |  |  | 3.9 |  | Voot 1.0 | $V$ |

## 11. RECOMMENDED SOLDERING CONDITIONS

Solder this product under the soldering conditions indicated below.
For further information on the recommended soldering conditions, refer to information document "SEMICONDUCTOR DEVICE MOUNTING TECHNOLOGY MANUAL (IEI-1207)".

For soldering methods and conditions other than those of recommended, consult NEC.

Table 11-1. Soldering Conditions for Types of Surface Mounting Device
(1) $\mu$ PD70108GC- $\times x-3 B 6$ : 52 -pin plastic QFP $(\square 14 \mathrm{~mm})$

| Soldering method | Soldering condition | Symbol |
| :---: | :---: | :---: |
| Infrared ray reflow | Peak temperature of package surface: $230{ }^{\circ} \mathrm{C}$, <br> Time: 30 seconds max. ( $210^{\circ} \mathrm{C}$ min. $)_{\text {, Number of reflow process: } 1}$ <br> Exposure limiteces: 7 days ( 10 hours pre-baking is required at $125^{\circ} \mathrm{C}$ afterwards) | IR30-107-1 |
| VPS | Peak temperature of package surface: $215^{\circ} \mathrm{C}$, <br> Time: 40 seconds max. $\left(200^{\circ} \mathrm{C}\right.$ min.) , Number of reflow process: 1 <br> Exposure limitwers: 7 days ( 10 hours pre-baking is required at $125{ }^{\circ} \mathrm{C}$ afterwards) | VP15-107-1 |
| Wave soldering | Solder temperature: $260^{\circ} \mathrm{C}$ max., Time: 10 seconds max., <br> Number of reflow process: 1 <br> Exposure limitwas: 7 days ( 10 hours pre-baking is required at $125{ }^{\circ} \mathrm{C}$ afterwards) <br> Preheating temperature: $120^{\circ} \mathrm{C}$ max. (package surface temperature) | WS60-107-1 |
| Partial heating | Pin temperature: $300{ }^{\circ} \mathrm{C}$ max., Time: 3 seconds max. (per one side of device) | - |

Note Exposure limit before soldering after dry-pack package is opened.
Storage conditions: $25^{\circ} \mathrm{C}$ and relative humidity at $\mathbf{6 5 \%}$ or less.

## Caution Do not apply two or more soldering methods (except partial heating) in combination.

- Information

Recommended soldering conditions for some parts of this product have been upgraded.
(Improvements mode: Infrared ray reflow peak temperature expansion $\left(235^{\circ} \mathrm{C}\right)$, twice, restrictions on days, etc.)
For details, consult NEC.
(2) $\mu$ PD $70108 L-x \times$ : 44-pin plastic QFJ $\square 650$ mil)

| Soldering method | Soldering condition | Symbol |
| :---: | :---: | :---: |
| Infrared ray refiow | Peak temperature of package surface: $230^{\circ} \mathrm{C}$, <br> Time: 30 seconds max. $\left(210^{\circ} \mathrm{C}\right.$ min.). Number of reflow process: 1 <br> Exposure limitwar: 7 days ( 10 hours pre-baking is required at $125^{\circ} \mathrm{C}$ afterwards) | IR30-107-1 |
| VPS | Peak temperature of package surface: $215{ }^{\circ} \mathrm{C}$, <br> Time: 40 seconds max. $\left(200^{\circ} \mathrm{C}\right.$ min.) , Number of reflow process: 1 <br> Exposure limit Nes: 7 days ( 10 hours pre-baking is required at $125^{\circ} \mathrm{C}$ afterwards) | VP15-107-1 |
| Partial heating | Pin temperature: $300^{\circ} \mathrm{C}$ max., Time: 3 seconds max. (per one side of device) | - |

Note Exposure limit before soldering after dry-pack package is opened.
Storage conditions: $25^{\circ} \mathrm{C}$ and relative humidity at $\mathbf{6 5 \%}$ or less.
Caution Do not apply two or more soldering methods (except partial heating) in combination.

Table 11－2．Soldering Conditions for Types of Insert Mounting Device
$\mu$ PD70108C－$\times x$ ：40－pin plastic DIP（ 600 mil）

| Soldering method | Soldering condition |
| :--- | :--- |
| Wave soldering <br> （Only leads） | Solder temperature： $260^{\circ} \mathrm{C}$ max．，Time： 10 seconds max． |
| Partial heating | Pin temperature： $260^{\circ} \mathrm{C}$ max．，Time： 10 seconds max． |

Caution Solder only the leads by means of wave soldering，and exercise care that the jetted solder does not come in contact with the package．
