Zero Cycle Slip Peak EMI reduction IC

General Features

- Input frequency range: 20MHz - 50MHz.
- Zero input - output propagation delay.
- Low-skew outputs.
 - Output-output skew less than 250pS.
 - Device-device skew less than 700pS.
- Less than 200pS cycle-to-cycle jitter is compatible with Pentium® based systems.
- Available in 16pin, 150mil SOIC, 4.4mm TSSOP (ASM3P623S00D/E/F), and in 8pin, 150 mil SOIC, 4.4mm TSSOP Packages (ASM3P623S00A/B/C).
- 3.3V operation
- Advanced 0.35μ CMOS technology.
- The First True Drop-in Solution.

All parts have on-chip PLLs that lock to an input clock on the CLKIN pin. The PLL feedback is on-chip and is obtained from the CLKOUT pad, internal to the device.

Multiple ASM3P623S00D/E/F devices can accept the same input clock and distribute it. In this case, the skew between the outputs of the two devices is guaranteed to be less than 700pS.

All outputs have less than 200pS of cycle-to-cycle jitter. The input and output propagation delay is guaranteed to be less than 250pS, and the output-to-output skew is guaranteed to be less than 250pS.

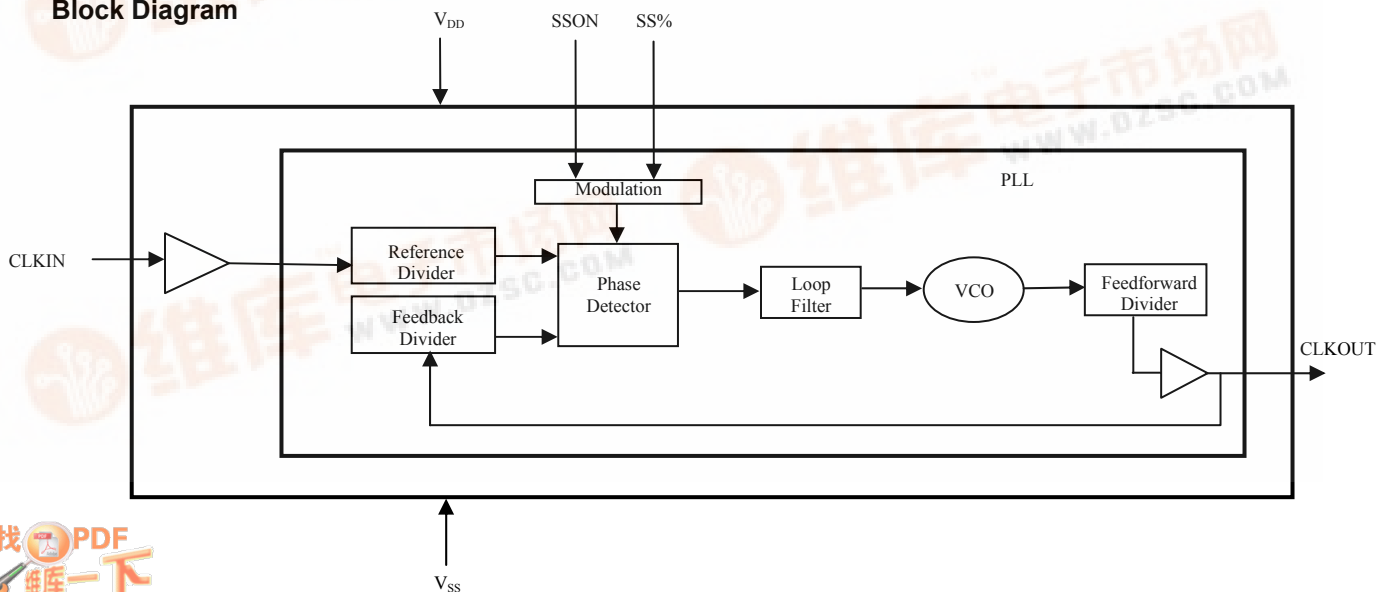

Please refer “Differential Cycle Slips and Spread Spectrum Control Table” for deviations and differential Cycle Slips for ASM3P623S00A/B/C and the ASM3P623S00D/E/F devices

Functional Description

ASM3P623S00D/E/F is a versatile, 3.3V zero-delay buffer designed to distribute high-speed clocks. It accepts one reference input and drives out eight low-skew clocks. It is available in a 16pin package. The ASM3P623S00A/B/C is the eight-pin version of the ASM3P623S00. It accepts one reference input and drives out one low-skew clock.

The ASM3P623S00A/B/C and the ASM3P623S00D/E/F are available in two different configurations, as shown in the ordering information table.

Block Diagram

Spread Spectrum Frequency Generation

The clocks in digital systems are typically square waves with a 50% duty cycle and as frequencies increase the edge rates also get faster. Analysis shows that a square wave is composed of fundamental frequency and harmonics. The fundamental frequency and harmonics generate the energy peaks that become the source of EMI. Regulatory agencies test electronic equipment by measuring the amount of peak energy radiated from the equipment. In fact, the peak level allowed decreases as the frequency increases. The standard methods of reducing EMI are to use shielding, filtering, multi-layer

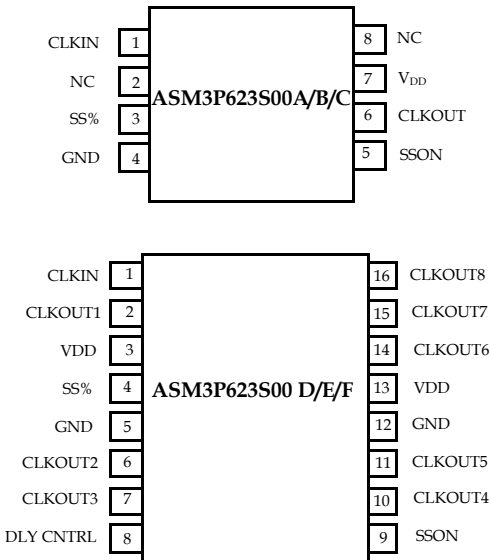

PCBs etc. These methods are expensive. Spread spectrum clocking reduces the peak energy by reducing the Q factor of the clock. This is done by slowly modulating the clock frequency. The ASM3P623S00X uses the center modulation spread spectrum technique in which the modulated output frequency varies above and below the reference frequency with a specified modulation rate. With center modulation, the average frequency is the same as the unmodulated frequency and there is no performance degradation

Cycle Slip

Cycle slip occurs when the output clock edge ‘wanders’ away from the corresponding input clock edge. There are two types of cycle slips – a Differential cycle slip and an Integral cycle slip. The differential cycle slip is caused due the clock edge variation over one modulation cycle. It is defined by the maximum amount of ‘wander’ the clock edge will have within one

modulation cycle. Integral cycle slip occurs due to the accumulation of the cycle slip over successive modulation cycles. In ASM3P623S00A/B/C/D/E/F the differential cycle slip is within the value mentioned in the “Differential Cycle Slip and Spread Spectrum Control Table” and the Integral Cycle Slip is ‘Zero’.
