

Single, 12-/14-/16-Bit *nanoDAC*™ with 5 ppm/°C On-Chip Reference in SOT-23

AD5620/AD5640/AD5660

FEATURES

Low power, single *nanoDAC*s

AD5660: 16 bits

AD5640: 14 bits

AD5620: 12 bits

12-bit accuracy guaranteed

On-chip, 1.25 V/2.5 V, 5 ppm/°C reference

Tiny 8-lead SOT-23/MSOP packages

Power-down to 480 nA @ 5 V, 200 nA @ 3 V

3 V/5 V single power supply

Guaranteed 16-bit monotonic by design

Power-on reset to zero/midscale

3 power-down functions

Serial interface with Schmitt-triggered inputs

Rail-to-rail operation

SYNC interrupt facility

APPLICATIONS

Process control

Data acquisition systems

Portable battery-powered instruments

Digital gain and offset adjustment

Programmable voltage and current sources

Programmable attenuators

PRODUCT HIGHLIGHTS

- 12-/14-/16-bit *nanoDAC*—12-bit accuracy guaranteed.
- On-chip, 1.25 V/2.5 V, 5 ppm/°C reference.
- Available in 8-lead SOT-23 and 8-lead MSOP packages.
- Power-on reset to 0 V or midscale.
- 10 μs settling time.

RELATED DEVICE

Part No.	Description
AD5662	2.7 V to 5.5 V, 16-bit DAC in SOT-23, external reference

FUNCTIONAL BLOCK DIAGRAM

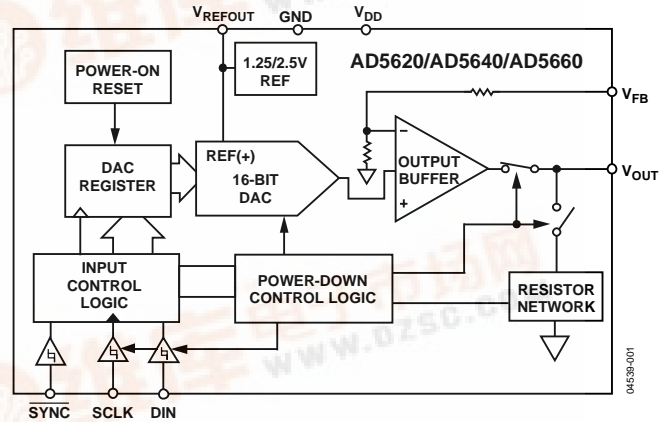

Figure 1.

GENERAL DESCRIPTION

The AD5620/AD5640/AD5660, members of the *nanoDAC* family of devices, are low power, single, 12-/14-/16-bit, buffered voltage-out DACs and are guaranteed monotonic by design.

The AD5620/AD5640/AD5660-1 parts include an internal, 1.25 V, 5 ppm/°C reference, giving a full-scale output voltage range of 2.5 V. The AD5620/AD5640/AD5660-2-3 parts include an internal, 2.5 V, 5 ppm/°C reference, giving a full-scale output voltage range of 5 V. The reference associated with each part is available at the V_{REFOUT} pin.

The parts incorporate a power-on reset circuit to ensure that the DAC output powers up to 0 V (AD5620/AD5640/AD5660-1-2) or midscale (AD5620-3 and AD5660-3) and remains there until a valid write takes place. The parts contain a power-down feature that reduces the current consumption of the device to 480 nA at 5 V and provides software-selectable output loads while in power-down mode. The power consumption is 2.5 mW at 5 V, reducing to 1 μW in power-down mode.

The AD5620/AD5640/AD5660 on-chip precision output amplifier allows rail-to-rail output swing to be achieved. For remote sensing applications, the output amplifier's inverting input is available to the user. The AD5620/AD5640/AD5660 use a versatile 3-wire serial interface that operates at clock rates up to 30 MHz and is compatible with standard SPI®, QSPI™, MICROWIRE™, and DSP interface standards.

V _{DD} = 2.7 V to 3.3 V	0.25	0.25	0.25	µA max	V _{IH} = V _{DD} and V _{IL} = GND

¹ Part is functional with V_{DD} up to 5.5 V.

² Temperature range is -15°C to +105°C, typical at +25°C.

³ Linearity calculated using a reduced code range: AD5660 (Code 511 to Code 65024); AD5640 (Code 128 to Code 16256); AD5620 (Code 32 to Code 4064). Output unloaded.

⁴ Guaranteed by design and characterization; not production tested.

TIMING CHARACTERISTICS

All input signals are specified with $t_r = t_f = 1 \text{ ns/V}$ (10% to 90% of V_{DD}) and timed from a voltage level of $(V_{IL} + V_{IH})/2$. See Figure 2. $V_{DD} = 2.7 \text{ V}$ to 5.5 V ; all specifications T_{MIN} to T_{MAX} , unless otherwise noted.

Table 3.

Parameter	Limit at T_{MIN}, T_{MAX}		Unit	Conditions/Comments
	$V_{DD} = 2.7 \text{ V to } 3.6 \text{ V}$	$V_{DD} = 3.6 \text{ V to } 5.5 \text{ V}$		
t_1^1	50	33	ns min	SCLK cycle time
t_2	13	13	ns min	SCLK high time
t_3	13	13	ns min	SCLK low time
t_4	13	13	ns min	$\overline{\text{SYNC}}$ to SCLK falling edge set-up time
t_5	5	5	ns min	Data set-up time
t_6	4.5	4.5	ns min	Data hold time
t_7	0	0	ns min	SCLK falling edge to $\overline{\text{SYNC}}$ rising edge
t_8	50	33	ns min	Minimum $\overline{\text{SYNC}}$ high time
t_9	13	13	ns min	$\overline{\text{SYNC}}$ rising edge to SCLK fall ignore
t_{10}	0	0	ns min	SCLK falling edge to $\overline{\text{SYNC}}$ fall ignore

¹ Maximum SCLK frequency is 30 MHz at $V_{DD} = 3.6 \text{ V}$ to 5.5 V and 20 MHz at $V_{DD} = 2.7 \text{ V}$ to 3.6 V .

ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$, unless otherwise noted.

Table 4.

Parameter	Rating
V_{DD} to GND	-0.3 V to +7 V
V_{OUT} to GND	-0.3 V to $V_{DD} + 0.3$ V
V_{FB} to GND	-0.3 V to $V_{DD} + 0.3$ V
V_{REFOUT} to GND	-0.3 V to $V_{DD} + 0.3$ V
Digital Input Voltage to GND	-0.3 V to $V_{DD} + 0.3$ V
Operating Temperature Range	
Industrial	-15°C to +105°C
Storage Temperature Range	-65°C to +150°C
Junction Temperature (T_J max)	150°C
Power Dissipation	$(T_J \text{ max} - T_A)/\theta_{JA}$
SOT-23 Package (4-Layer Board)	
θ_{JA} Thermal Impedance	119°C/W
MSOP Package (4-Layer Board)	
θ_{JA} Thermal Impedance	141°C/W
θ_{JC} Thermal Impedance	44°C/W
Reflow Soldering Peak Temperature	
SnPb	240°C
Pb-Free	260°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

Figure 3. SOT-23 Pin Configuration

Figure 4. MSOP Pin Configuration

Table 5. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	V_{DD}	Power Supply Input. These parts can operate from 2.7 V to 5.5 V. V_{DD} should be decoupled to GND.
2	V_{REFOUT}	Reference Voltage Output.
3	V_{FB}	Feedback Connection for the output amplifier. V_{FB} should be connected to V_{OUT} for normal operation.
4	V_{OUT}	Analog Output Voltage from DAC. The output amplifier has rail-to-rail operation.
5	\overline{SYNC}	Level-Triggered Control Input (Active Low). This is the frame synchronization signal for the input data. When \overline{SYNC} goes low, it enables the input shift register and data is transferred in on the falling edges of the following clocks. The DAC is updated following the 24 th clock cycle for the AD5660 and the 16 th clock cycle for AD5620/AD5640 unless \overline{SYNC} is taken high before this edge. In this case, the rising edge of \overline{SYNC} acts as an interrupt, and the write sequence is ignored by the DAC.
6	SCLK	Serial Clock Input. Data is clocked into the input shift register on the falling edge of the serial clock input. Data can be transferred at rates up to 30 MHz.
7	DIN	Serial Data Input. The AD5660 has a 24-bit shift register, and the AD5620/AD5640 have a 16-bit shift register. Data is clocked into the register on the falling edge of the serial clock input.
8	GND	Ground Reference Point for all circuitry on the part.

TERMINOLOGY

Relative Accuracy

For the DAC, relative accuracy, or integral nonlinearity (INL), is a measurement of the maximum deviation, in LSBs, from a straight line passing through the endpoints of the DAC transfer function. Figure 5 through Figure 7 show typical INL vs. code.

Differential Nonlinearity (DNL)

Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of ± 1 LSB maximum ensures monotonicity. This DAC is guaranteed monotonic by design. Figure 8 through Figure 10 show typical DNL vs. code.

Zero-Code Error

Zero-code error is a measurement of the output error when zero code (0x0000) is loaded to the DAC register. Ideally, the output should be 0 V. The zero-code error is always positive in the AD5620/AD5640/AD5660, because the output of the DAC cannot go below 0 V. It is due to a combination of the offset errors in the DAC and the output amplifier. Zero-code error is expressed in mV. Figure 19 shows a plot of zero-code error vs. temperature.

Full-Scale Error

Full-scale error is a measurement of the output error when full-scale code (0xFFFF) is loaded to the DAC register. Ideally, the output should be $V_{DD} - 1$ LSB. Full-scale error is expressed as a percentage of the full-scale range. Figure 18 shows a plot of full-scale error vs. temperature.

Gain Error

This is a measurement of the span error of the DAC. It is the deviation in slope of the DAC transfer characteristic from the ideal, expressed as a percentage of the full-scale range.

Zero-Code Error Drift

This is a measurement of the change in zero-code error with a change in temperature. It is expressed in $\mu\text{V}/^\circ\text{C}$.

Gain Temperature Coefficient

This is a measurement of the change in gain error with changes in temperature. It is expressed in (ppm of full-scale range)/ $^\circ\text{C}$.

Offset Error

Offset error is a measurement of the difference between V_{OUT} (actual) and V_{OUT} (ideal) expressed in mV in the linear region of the transfer function. Offset error is measured on the AD5660 with Code 512 loaded into the DAC register. It can be negative or positive.

DC Power Supply Rejection Ratio (PSRR)

This indicates how the output of the DAC is affected by changes in the supply voltage. PSRR is the ratio of the change in V_{OUT} to the change in V_{DD} for the full-scale output of the DAC. It is measured in dB. V_{REF} is held at 2.5 V, and V_{DD} is varied by $\pm 10\%$.

Output Voltage Settling Time

This indicates the amount of time for the output of a DAC to settle to a specified level for a $\frac{1}{4}$ to $\frac{3}{4}$ full-scale input change. It is measured from the 24th falling edge of SCLK.

Digital-to-Analog Glitch Impulse

Digital-to-analog glitch impulse is the impulse injected into the analog output when the input code in the DAC register changes state. It is normally specified as the area of the glitch in nV-s and is measured when the digital input code is changed by 1 LSB at the major carry transition (0x7FFF to 0x8000). See Figure 31 and Figure 32.

Digital Feedthrough

Digital feedthrough is a measurement of the impulse injected into the analog output of the DAC from the digital inputs of the DAC, but is measured when the DAC output is not updated. It is specified in nV-s and measured with a full-scale code change on the data bus, that is, from all 0s to all 1s or vice versa.

Noise Spectral Density

This is a measurement of the internally generated random noise. Random noise is characterized as a spectral density (voltage per $\sqrt{\text{Hz}}$). It is measured by loading the DAC to midscale and measuring noise at the output. It is measured in $\text{nV}/\sqrt{\text{Hz}}$. Figure 37 shows a plot of noise spectral density.

THEORY OF OPERATION

D/A SECTION

The AD5620/AD5640/AD5660 DACs are fabricated on a CMOS process. The architecture consists of a string DAC followed by an output buffer amplifier. The parts include an internal 1.25 V/2.5 V, 5 ppm/°C reference that is internally gained up by 2. Figure 38 shows a block diagram of the DAC architecture.

Figure 38. DAC Architecture

Because the input coding to the DAC is straight binary, the ideal output voltage is given by

$$V_{OUT} = 2 \times V_{REFOUT} \times \left(\frac{D}{2^N} \right)$$

where:

D is the decimal equivalent of the binary code that is loaded to the DAC register.

0 to 4,095 for AD5620 (12 bit)

0 to 16,383 for AD5640 (14 bit)

0 to 65,535 for AD5660 (16 bit)

N is the DAC resolution.

Figure 39. Resistor String

RESISTOR STRING

The resistor string section is shown in Figure 39. It is simply a string of resistors, each of value R . The code loaded to the DAC register determines at which node on the string the voltage is tapped off to be fed into the output amplifier. The voltage is

tapped off by closing one of the switches connecting the string to the amplifier. Because it is a string of resistors, it is guaranteed monotonic.

INTERNAL REFERENCE

The AD5620/AD5640/AD5660-1 parts include an internal, 1.25 V, 5 ppm/°C reference, giving a full-scale output voltage of 2.5 V. The AD5620/AD5640/AD5660-2-3 parts include an internal, 2.5 V, 5 ppm/°C reference, giving a full-scale output voltage of 5 V. The reference associated with each part is available at the V_{REFOUT} pin. A buffer is required if the reference output is used to drive external loads. It is recommended that a 100 nF capacitor is placed between the reference output and GND for reference stability.

OUTPUT AMPLIFIER

The output buffer amplifier can generate rail-to-rail voltages on its output, which gives an output range of 0 V to V_{DD} . This output buffer amplifier has a gain of 2 derived from a 50 kΩ resistor divider network in the feedback path. The inverting input of the output amplifier is available to the user, allowing for remote sensing. This V_{FB} pin must be connected to V_{OUT} for normal operation. It can drive a load of 2 kΩ in parallel with 1,000 pF to GND. Figure 21 shows the source and sink capabilities of the output amplifier. The slew rate is 1.5 V/μs with a ¼ to ¾ full-scale settling time of 10 μs.

SERIAL INTERFACE

The AD5620/AD5640/AD5660 have a 3-wire serial interface ($\overline{\text{SYNC}}$, SCLK, and DIN) that is compatible with SPI, QSPI, and MICROWIRE interface standards as well as most DSPs.

See Figure 2 for a timing diagram of a typical write sequence.

The write sequence begins by bringing the $\overline{\text{SYNC}}$ line low.

Data from the DIN line is clocked into the 16-bit shift register (AD5620/AD5640) or the 24-bit shift register (AD5660) on the falling edge of SCLK. The serial clock frequency can be as high as 30 MHz, making the AD5620/AD5640/AD5660 compatible with high speed DSPs. On the 16th falling clock edge (AD5620/AD5640) or the 24th falling clock edge (AD5660), the last data bit is clocked in and the programmed function is executed, that is, a change in the DAC register contents and/or a change in the mode of operation is executed. At this stage, the $\overline{\text{SYNC}}$ line can be kept low or be brought high. In either case, it must be brought high for a minimum of 33 ns before the next write sequence so that a falling edge of $\overline{\text{SYNC}}$ can initiate the next write sequence. Because the $\overline{\text{SYNC}}$ buffer draws more current when $V_{IN} = 2$ V than it does when $V_{IN} = 0.8$ V, $\overline{\text{SYNC}}$ should be idled low between write sequences for even lower power operation of the parts. As is mentioned previously, however, $\overline{\text{SYNC}}$ must be brought high again just before the next write sequence.

AD5620/AD5640/AD5660

INPUT SHIFT REGISTER

AD5620/AD5640

The input shift register is 16 bits wide for the AD5620/AD5640 (see Figure 40 and Figure 41). The first two bits are control bits that control which mode of operation the part is in (normal mode or any of the three power-down modes). The next 14/12 bits, respectively, are the data bits. These are transferred to the DAC register on the 16th falling edge of SCLK.

AD5660

The input shift register is 24 bits wide for the AD5660 (see Figure 42). The first six bits are don't care bits. The next two are control bits that control which mode of operation the part is in (normal mode or any of the three power-down modes). For a more complete description of the various modes, see the Power-Down Modes section. The next 16 bits are the data bits. These are transferred to the DAC register on the 24th falling edge of SCLK.

SYNC INTERRUPT

In a normal write sequence for the AD5660, the $\overline{\text{SYNC}}$ line is kept low for at least 24 falling edges of SCLK, and the DAC is updated on the 24th falling edge. However, if $\overline{\text{SYNC}}$ is brought high before the 24th falling edge, this acts as an interrupt to the write sequence. The shift register is reset, and the write sequence is seen as invalid. Neither an update of the DAC register contents nor a change in the operating mode occurs—see Figure 43. Similarly, in a normal write sequence for the AD5620/AD5640, the $\overline{\text{SYNC}}$ line is kept low for at least 16 falling edges of SCLK, and the DAC is updated on the 16th falling edge. However, if $\overline{\text{SYNC}}$ is brought high before the 16th falling edge, this acts as an interrupt to the write sequence.

Figure 43. $\overline{\text{SYNC}}$ Interrupt Facility

POWER-ON RESET

The AD5620/AD5640/AD5660 family contains a power-on reset circuit that controls the output voltage during power-up. The AD5620/AD5640/AD5660-1-2 DAC output powers up to 0 V, and the AD5620/AD5660-3 DAC output powers up to midscale. The output remains at this level until a valid write sequence is made to the DAC, which is useful in applications where it is important to know the state of the DAC output while it is in the process of powering up.

POWER-DOWN MODES

The AD5620/AD5640/AD5660 have four separate modes of operation. These modes are software-programmable by setting two bits in the control register. Table 6 and Table 7 show how the state of the bits corresponds to the operating mode of the device.

Table 6. Modes of Operation for the AD5660

DB17	DB16	AD5660 Operating Mode
0	0	Normal operation
		Power-down modes:
0	1	1 kΩ to GND
1	0	100 kΩ to GND
1	1	Three-state

Table 7. Modes of Operation for the AD5620/AD5640

DB15	DB14	AD5620/AD5640 Operating Mode
0	0	Normal operation
		Power-down modes:
0	1	1 kΩ to GND
1	0	100 kΩ to GND
1	1	Three-state

When both bits are set to 0, the part works normally with its normal power consumption of 550 μA at 5 V. However, for the three power-down modes, the supply current falls to 480 nA at 5 V (200 nA at 3 V). Not only does the supply current fall, but the output stage is internally switched from the output of the amplifier to a resistor network of known values. The advantage is that the output impedance of the part is known while the part is in power-down mode. There are three options: the output is connected internally to GND through a 1 kΩ or a 100 kΩ resistor, or it is left open-circuited (three-stated). The output stage is shown in Figure 44.

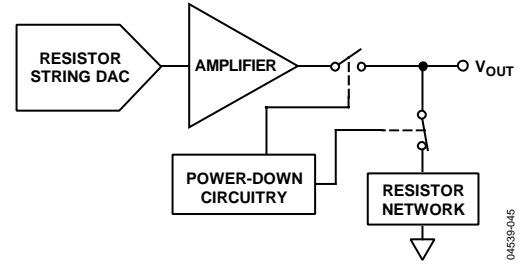

Figure 44. Output Stage During Power-Down

The bias generator, output amplifier, reference, resistor string, and other associated linear circuitry are all shut down when power-down mode is activated. However, the contents of the DAC register are unaffected when in power-down. The time to exit power-down is typically 5 μs for $V_{DD} = 5\text{ V}$ and $V_{DD} = 3\text{ V}$. See Figure 23.

MICROPROCESSOR INTERFACING

AD5660-to-Blackfin® ADSP-BF53x Interface

Figure 45 shows a serial interface between the AD5660 and the Blackfin ADSP-BF53x microprocessor. The ADSP-BF53x processor family incorporates two dual-channel synchronous serial ports, SPORT1 and SPORT0, for serial and multi-processor communications. Using SPORT0 to connect to the AD5660, the setup for the interface is as follows: DTOPRI drives the DIN pin of the AD5660, while TSCLK0 drives the SCLK of the part and SYNC is driven from TFS0.

¹ ADDITIONAL PINS OMITTED FOR CLARITY

Figure 45. AD5660-to-Blackfin ADSP-BF53x Interface

AD5620/AD5640/AD5660

AD5660-to-68HC11/68L11 Interface

Figure 46 shows a serial interface between the AD5660 and the 68HC11/68L11 microcontroller. SCK of 68HC11/68L11 drives the SCLK of AD5660, and the MOSI output drives the serial data line of the DAC. The SYNC signal is derived from a port line (PC7). The set-up conditions for correct operation of this interface are as follows: The 68HC11/68L11 should be configured so that its CPOL bit is 0, and its CPHA bit is 1. When data is being transmitted to the DAC, the SYNC line is taken low (PC7). When the 68HC11/68L11 is configured in this way, data appearing on the MOSI output is valid on the falling edge of SCK. Serial data from the 68HC11/68L11 is transmitted in 8-bit bytes with only eight falling clock edges occurring in the transmit cycle. Data is transmitted MSB first. To load data to the AD5660, PC7 is left low after the first eight bits are transferred, a second serial write operation is performed to the DAC, and PC7 is taken high at the end of this procedure.

¹ ADDITIONAL PINS OMITTED FOR CLARITY

Figure 46. AD5660-to-68HC11/68L11 Interface

AD5660-to-80C51/80L51 Interface

Figure 47 shows a serial interface between the AD5660 and the 80C51/80L51 microcontroller. The setup for the interface is as follows: TxD of the 80C51/80L51 drives SCLK of the AD5660, and RxD drives the serial data line of the part. The SYNC signal is again derived from a bit-programmable pin on the port. In this case, Port Line P3.3 is used. When data is to be transmitted to the AD5660, P3.3 is taken low. The 80C51/80L51 transmit data only in 8-bit bytes; therefore, only eight falling clock edges

occur in the transmit cycle. To load data to the DAC, P3.3 is left low after the first eight bits are transmitted, and a second write cycle is initiated to transmit the second byte of data. P3.3 is taken high following the completion of this cycle. The 80C51/80L51 output the serial data LSB first; however, the AD5660 requires its data with the MSB as the first bit received. The 80C51/80L51 transmit routine should take this into account.

¹ ADDITIONAL PINS OMITTED FOR CLARITY

Figure 47. AD5660-to-80C51/80L51 Interface

AD5660-to-MICROWIRE Interface

Figure 48 shows an interface between the AD5660 and any MICROWIRE-compatible device. Serial data is shifted out on the falling edge of the serial clock and is clocked into the AD5660 on the rising edge of the SK.

Figure 48. AD5660-to-MICROWIRE Interface

APPLICATIONS

USING AN REF19x AS A POWER SUPPLY FOR THE AD5620/AD5640/AD5660

Because the supply current required by the AD5620/AD5640/AD5660 is extremely low, an alternative option is to use a REF19x voltage reference (REF195 for 5 V or REF193 for 3 V) to supply the required voltage to the part—see Figure 49. This is especially useful if the power supply is quite noisy or if the system supply voltages are at some value other than 5 V or 3 V, for example, 15 V. The REF19x outputs a steady supply voltage for the AD5620/AD5640/AD5660. If the low dropout REF195 is used, the current it needs to supply to the AD5660 is 500 μ A. This is with no load on the output of the DAC. When the DAC output is loaded, the REF195 also must supply the current to the load. The total current required (with a 5 k Ω load on the DAC output) is

$$500 \mu\text{A} + (5 \text{ V} / 5 \text{ k}\Omega) = 1.5 \text{ mA}$$

The load regulation of the REF195 is typically 2 ppm/mA, which results in an error of 3 ppm (15 μ V) for the 1.5 mA current drawn from it. This corresponds to a 0.197 LSB error for the AD5660.

Figure 49. REF195 as the Power Supply to the AD5660

BIPOLAR OPERATION USING THE AD5660

The AD5660 is designed for single-supply operation, but a bipolar output range is also possible using the circuit in Figure 50. Figure 50 gives an output voltage range of ± 5 V. Rail-to-rail operation at the amplifier output is achievable using an AD820 or an OP295 as the output amplifier.

The output voltage for any input code can be calculated as

$$V_o = \left[V_{DD} \times \left(\frac{D}{65536} \right) \times \left(\frac{R1 + R2}{R1} \right) - V_{DD} \times \left(\frac{R2}{R1} \right) \right]$$

where D represents the input code in decimal (0 to 65,535).

When $V_{DD} = 5$ V, $R1 = R2 = 10$ k Ω ,

$$V_o = \left(\frac{10 \times D}{65536} \right) - 5 \text{ V}$$

This results in an output voltage range of ± 5 V, with 0x0000 corresponding to a -5 V output and 0xFFFF corresponding to a $+5$ V output.

Figure 50. Bipolar Operation with the AD5660

USING THE AD5660 AS AN ISOLATED, PROGRAMMABLE, 4 TO 20 mA PROCESS CONTROLLER

In many process-control system applications, 2-wire current transmitters are used to transmit analog signals through noisy environments. These current transmitters use a zero-scale signal current of 4 mA to power the signal conditioning circuitry of the transmitter. The full-scale output signal in these transmitters is 20 mA. The converse approach to process control can also be used, in which a low-power, programmable current source is used to control remotely located sensors or devices in the loop.

A circuit that performs this function is shown in Figure 51. Using the AD5660 as the controller, the circuit provides a programmable output current of 4 to 20 mA, proportional to the digital code of the DAC. Biasing for the controller is provided by the ADR02 and requires no external trim for two reasons: first, the ADR02's tight initial output voltage tolerance, and second, the low supply current consumption of both the AD8627 and the AD5660. The entire circuit, including optocouplers, consumes less than 3 mA from the total budget of 4 mA. The AD8627 regulates the output current to satisfy the current summation at the noninverting node of the AD8627.

$$I_{OUT} = 1/R7 (V_{DAC} \times R3/R1 + V_{REF} \times R3/R2)$$

For the values shown in Figure 51,

$$I_{OUT} = 0.2435 \mu\text{A} \times D + 4 \text{ mA}$$

where $D = 0 \leq D \leq 65,535$, giving a full-scale output current of 20 mA when the AD5660's digital code equals 0xFFFF.

Offset trim at 4 mA is provided by P2, and P1 provides the circuit gain trim at 20 mA. These two trims do not interact because the noninverting input of the AD8627 is at virtual ground. The Schottky diode, D1, is required in this circuit to prevent loop supply power-on transients from pulling the noninverting input of the AD8627 more than 300 mV below its inverting input. Without this diode, such transients could cause phase reversal

AD5620/AD5640/AD5660

of the AD8627 and possible latch-up of the controller. The loop supply voltage compliance of the circuit is limited by the maximum applied input voltage to the ADR02 and is from 12 V to 40 V.

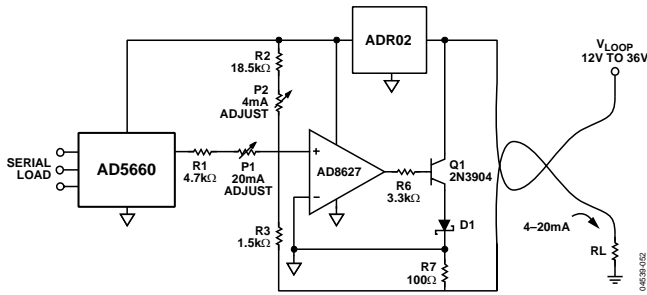

Figure 51. Programmable 4 to 20 mA Process Controller

USING THE AD5620/AD5640/AD5660 WITH A GALVANICALLY ISOLATED INTERFACE

For process-control applications in industrial environments, it is often necessary to use a galvanically isolated interface to protect and isolate the controlling circuitry from hazardous common-mode voltages that might occur in the area where the DAC is functioning. The *iCoupler*® provides isolation in excess of 2.5 kV. The AD5620/AD5640/AD5660 use a 3-wire serial logic interface; therefore, the ADuM1300 3-channel digital isolator provides the required isolation (see Figure 52). The power supply to the part also must be isolated, which is done by using a transformer. On the DAC side of the transformer, a 5 V regulator provides the 5 V supply required for the AD5620/AD5640/AD5660.

Figure 52. AD5620/AD5640/AD5660 with a Galvanically Isolated Interface

POWER SUPPLY BYPASSING AND GROUNDING

When accuracy is important in a circuit, it is helpful to carefully consider the power supply and ground return layout on the board. The printed circuit board containing the AD5620/AD5640/AD5660 should have separate analog and digital sections, each having its own area of the board. If the AD5620/AD5640/AD5660 are in a system where other devices require an AGND-to-DGND connection, the connection should be made at one point only. This ground point should be as close as possible to the AD5620/AD5640/AD5660.

The power supply to the AD5620/AD5640/AD5660 should be bypassed with 10 µF and 0.1 µF capacitors. The capacitors should be as close as physically possible to the device, with the 0.1 µF capacitor ideally right up against the device. The 10 µF capacitors are the tantalum bead type. It is important that the 0.1 µF capacitor has a low effective series resistance (ESR) and low effective series inductance (ESI), such as is typical of common ceramic types of capacitors. This 0.1 µF capacitor provides a low impedance path to ground for high frequencies caused by transient currents due to internal logic switching.

The power supply line itself should have as large a trace as possible to provide a low impedance path and reduce glitch effects on the supply line. Clocks and other components with fast switching digital signals should be shielded from other parts of the board by digital ground. Avoid crossover of digital and analog signals if possible. When traces cross on opposite sides of the board, ensure that they run at right angles to each other to reduce feedthrough effects on the board. The best board layout technique is the microstrip technique, where the component side of the board is dedicated to the ground plane only and the signal traces are placed on the solder side. However, this is not always possible with a 2-layer board.
