- Notes: 1. Stresses beyond those listed under Absolute Maximum Ratings could cause permanent damage to the device. Prolonged exposure to levels above the operating limits but below the Absolute Maximums may affect device reliability.
2. CMOS level input, nominal trip point is VDD/2 for 3.3 V or 5 V operation.

External Components

The ICS650R-14B requires a minimum number of external components for proper operation. Decoupling capacitors of 0.01µF should be connected between each VDD and GND on Pins 4 and 6, and Pins 16 and 14, as close to the ICS650R-14B as possible. A series termination resistor of 33 Ω may be used for each clock output. The 25.00 MHz crystal must be connected as close to the chip as possible. The crystal should be a fundamental mode (do not use third overtone), parallel resonant. Crystal capacitors should be connected from pins X1 to ground and X2 to ground to optimize the initial accuracy. The value of these capacitors is given by the following equation, where C_L is the crystal load capacitance: Crystal caps (pF) = $(C_L - 6) \times 2$. So for a crystal with 16 pF load capacitance, two 20 pF caps should be used.
