High Speed 16-Bit Port Link Bus Provides Simple

Interface Between Host and Modem Pool

INTRODUCTION

The ADSP-21mod870-110 is a complete single chip. All datapump and controller functions are implemented on a single 0.4 square-inch chip. This modem package allows the highest modem port density, while achieving the lowest power consumption in a software upgradable platform.

The ADSP-21mod870-110 is designed for high density systems such as remote access servers (see Figure 1). Its high performance DSP core, large on-chip SRAM, TDM serials port and 16-bit DMA port provide efficient control and data communication with minimal chip count. The modem software provides a number of data modulations, such as V.34, 56K bps PCM, and ISDN with a software upgrade path to future standards, and new applications, such as voice over network. The host interface allows system access to modem statistics such as call progress, connect speed and modulation parameters such as retrain count and symbol rate.

ON-CHIP SRAM

The ADSP-21mod870-110 processor integrates 160K bytes of on-chip memory. The modem datapump and controller software, as well as data storage, are contained in the on-chip SRAM. The SRAM cells are designed by Analog Devices. These cells are optimized for high speed digital signal processing and low power consumption. You can dynamically configure the ADSP-21mod870 with software through the 16-bit DMA interface.

DMA INTERFACE

The 16-bit internal DMA port (IDMA port) provides transparent, direct access to the on-chip RAM of the ADSP-21mod870 processor. This high speed access to on-chip memory simplifies control and data communication and system debug. Use the 16-bit DMA interface to dynamically configure the ADSP-21mod870 with software.

K56Flex is a trademark of Rockwell International and Lucent Technologies.

SERIAL PORTS

The ADSP-21mod870 processor incorporates two complete synchronous, double-buffered serial ports for serial communications. The serial ports interface directly to a time-division multiplexed (TDM) 1544 kbps (T1) or 2048 kbps (E1) serial stream, to an 8K sample/s data stream, or to an 8-bit companded (64 kb/s) data stream (DS0). The serial ports operate under modem software control.

SUPPORTED SYSTEM ARCHITECTURES

The ADSP-21mod870-110 Internet Gateway Processor Software supports two system architectures: *serial Telco PCM TDM data stream* and *parallel Telco PCM data stream*. The two architectures are differentiated by the method of proving Telco PCM data to the DSP Modem.

Serial Telco PCM TDM Data Stream Architecture

The serial Telco PCM TDM data stream architecture, shown in Figure 2, is the most common architecture. In this architecture, the modem pool may have a local Telco interface that provides a serial TDM data stream of Telco PCM data to the DSP through the DSP's Serial Port. You can connect up to 24/32 DSPs, through the Serial Port, to a 24/32 channel serial TDM data stream.

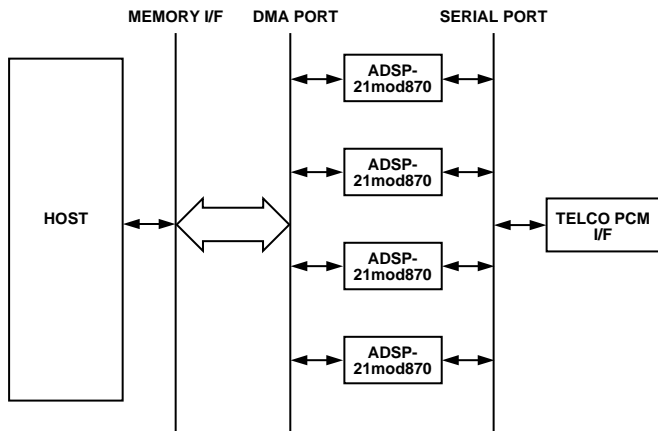

Figure 2. Serial Telco PCM TDM Data Stream Architecture

Parallel Telco PCM Data Stream Architecture

The parallel Telco PCM data stream architecture, shown in Figure 3, provides a single bus interface for all data and control. In this architecture, the modem pool may have a remote Telco interface that provides a parallel data stream of Telco PCM data to the DSP through the DSP's DMA Port. An arbitrary number of DSPs can be connected, through the DMA Port, to a Host that provides the parallel data stream.

Note: The number of parallel DSPs is limited only by the software loading constraints on the Host.

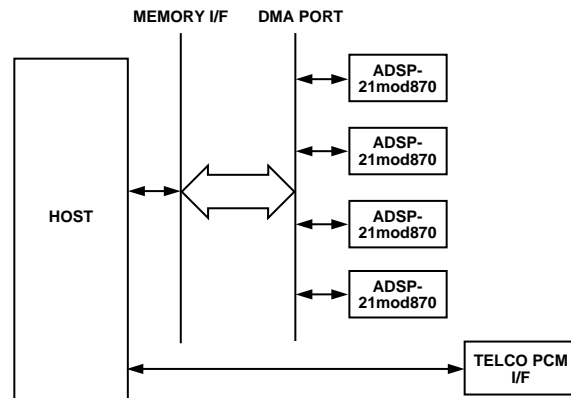

Figure 3. Parallel Telco PCM Data Stream Architecture

SOFTWARE INTERFACE

Analog Devices provides sample C code for the software interface to the ADSP-21mod870-110. The software interface encompasses the following four areas—download, control interface, data interface and modem statistics.

Download

The IDMA port on the ADSP-21mod870-110 contains an autoincrementing address generator. The host writes the starting address of the transfer and then writes the first word of data. After the first write, the IDMA address generator automatically increments; the host writes the next data word and the IDMA transfers that word to the next location in ADSP-21mod870-110 memory.

The executable image contains code and data that must be loaded into program and data memory. Program memory on the ADSP-21mod870-110 is 24 bits wide, therefore two transfers are used to load each word of program memory.

The host begins the download by asserting the $\overline{\text{RESET}}$ pin of the ADSP-21mod870-110. The host then transfers all code and data. All internal memory can be loaded in 5 ms.

Control Interface

The ADSP-21mod870-110 is controlled through two FIFOs in DSP memory. The host sends a control event by writing to the *host-to-modem* FIFO. The ADSP-21mod870-110 posts events to the host by writing into the *modem-to-host* FIFO.

Data Interface

All data transferred to and from the ADSP-21mod870-110 passes through word FIFOs located in internal memory on the ADSP-21mod870. The FIFOs are accessed through a control structure that contains a pointer to the start of the FIFO in memory, the length of the FIFO in 16-bit words, a pointer to the next address to be read, and a pointer to the next address to be written. The transmit and receive FIFOs are 1024 bytes deep. Example code providing primitives for accessing the byte-FIFOs is available from Analog Devices. Table I shows an example of a data FIFO.

Table I. FIFO Example

Modem Statistics

Several modem statistics can be gathered through the IDMA port. These statistics include call status, modulation in use, connect rate, transmit and receive data rate, symbol rate, retrain count, rate renegotiation count and others. Table II and Table IV contain a complete listing of available modem statistics.

Modem Configuration

The modem is configured by programming various parameters through the IDMA port. Table III and Table V contain complete lists of modem configuration parameters.

Table II. Shell Status
