

Low-Drop Fixed Voltage Regulator

TLE 4299

Data Sheet

Features

- Output voltage $3.3\text{V} \pm 2\%$
- 150 mA Output current
- Extreme low current consumption in ON state
- Inhibit function: Below $1\text{ }\mu\text{A}$ current consumption in off mode
- Early warning
- Reset output low down to $V_Q = 1\text{ V}$
- Overtemperature protection
- Reverse polarity proof
- Wide temperature range

Type	Ordering Code	Package
TLE 4299 GV33	Q67065-A7033	P-DSO-8-3
TLE 4299 GMV33	Q67065-A7032	P-DSO-14-8

Functional Description

The TLE 4299 is a monolithic voltage regulator with fixed 5-V (see data sheet TLE4299G/GM) or 3.3 V output, supplying loads up to 150 mA. It is especially designed for applications that may not be powered down while the motor is off. In addition the TLE 4299GMV includes an inhibit function. When the inhibit signal is removed, the device is switched off and the quiescent current is less than $1\text{ }\mu\text{A}$. To achieve proper operation of the μ -controller, the device supplies a reset signal. The reset delay time is selected application-specific by an external delay capacitor. The reset threshold is adjustable. An early warning signal supervises the voltage at pin SI. The TLE 4299 is pin-compatible to the TLE 4269 and functional similar with the additional inhibit function. The TLE 4299 is designed to supply microcontroller systems even under automotive environment conditions. Therefore it is protected against overload, short circuit and over temperature.

Circuit Description

The TLE 4299 is a PNP based very low drop linear voltage regulator. It regulates the output voltage to $V_Q = 3.3\text{ V}$ for an input voltage range of $4.4\text{ V} \leq V_I \leq 45\text{ V}$. The control circuit protects the device against potential damages caused by overcurrent and overtemperature.

The internal control circuit achieves a 3.3 V output voltage with a tolerance of $\pm 2\%$.

The device includes a power on reset and an under voltage reset function with adjustable reset delay time and adjustable reset switching threshold as well as a sense control/early warning function. The device includes an inhibit function to disable it when the ECU is not used for example while the motor is off.

The reset logic compares the output voltage V_Q to an internal threshold. If the output voltage drops below this level, the external reset delay capacitor C_D is discharged. When V_D is lower than V_{ST} , the reset output RO is switched Low. If the output voltage drop is very short, the V_{ST} level is not reached and no reset-signal is asserted. This feature avoids resets at short negative spikes at the output voltage e.g. caused by load changes.

As soon as the output voltage is more positive than the reset threshold, the delay capacitor is charged with constant current. When the voltage reaches V_{DT} the reset output RO is set High again.

The reset delay time and the reset reaction time are defined by the external capacitor C_D . The reset function is active down to $V_I = 1\text{ V}$.

In addition to the normal reset function, the device gives an early warning. When the SI voltage drops below $V_{SI,low}$, the device asserts the SI output Low to indicate the logic and the μ -processor that this voltage has dropped. The sense function uses a hysteresis: When the SI-voltage reaches the $V_{SI,high}$ level, SO is set high again. This feature can be used as early warning function to notice the μ -controller about a battery voltage drop and a possible reset in a short time. Of course also any other voltage can be observed by this feature.

The user defines the threshold by the resistor-values R_{SI1} and R_{SI2} .

For the exact timing and calculation of the reset and sense timing and thresholds, please refer to the application section.

Sense threshold low	$V_{SI \text{ low}}$	1.26	1.36	1.44	V	–
Sense input switching hysteresis	$V_{SI \text{ HYST}}$	50	90	130	mV	$V_{SI \text{ HYST}} = V_{SI \text{ high}} - V_{SI \text{ low}}$
Sense output low voltage	$V_{SO \text{ low}}$	–	0.1	0.4	V	$V_{SI} < 1.20 \text{ V}$; $V_i > 4.2 \text{ V}$; $I_{SO} = 1 \text{ mA}$
External SO pull up resistor	$R_{SO \text{ ext}}$	5.6	–	–	k Ω	–
Sense input current	I_{SI}	– 1	0.1	1	μA	$V_i > 1.0\text{V}$
Sense high reaction time	$t_{pd \text{ SO LH}}$	–	2.4	4.0	μs	$R_{SO \text{ ext}} = 5.6\text{k}\Omega$
Sense low reaction time	$t_{pd \text{ SO HL}}$	–	2.5	6.0	μs	$R_{SO \text{ ext}} = 5.6\text{k}\Omega$

Note: The listed characteristics are ensured over the operating range of the integrated circuit. Typical characteristics specify mean values expected over the production spread. If not otherwise specified, typical characteristics apply at $T_A = 25^\circ\text{C}$ and the given supply voltage.

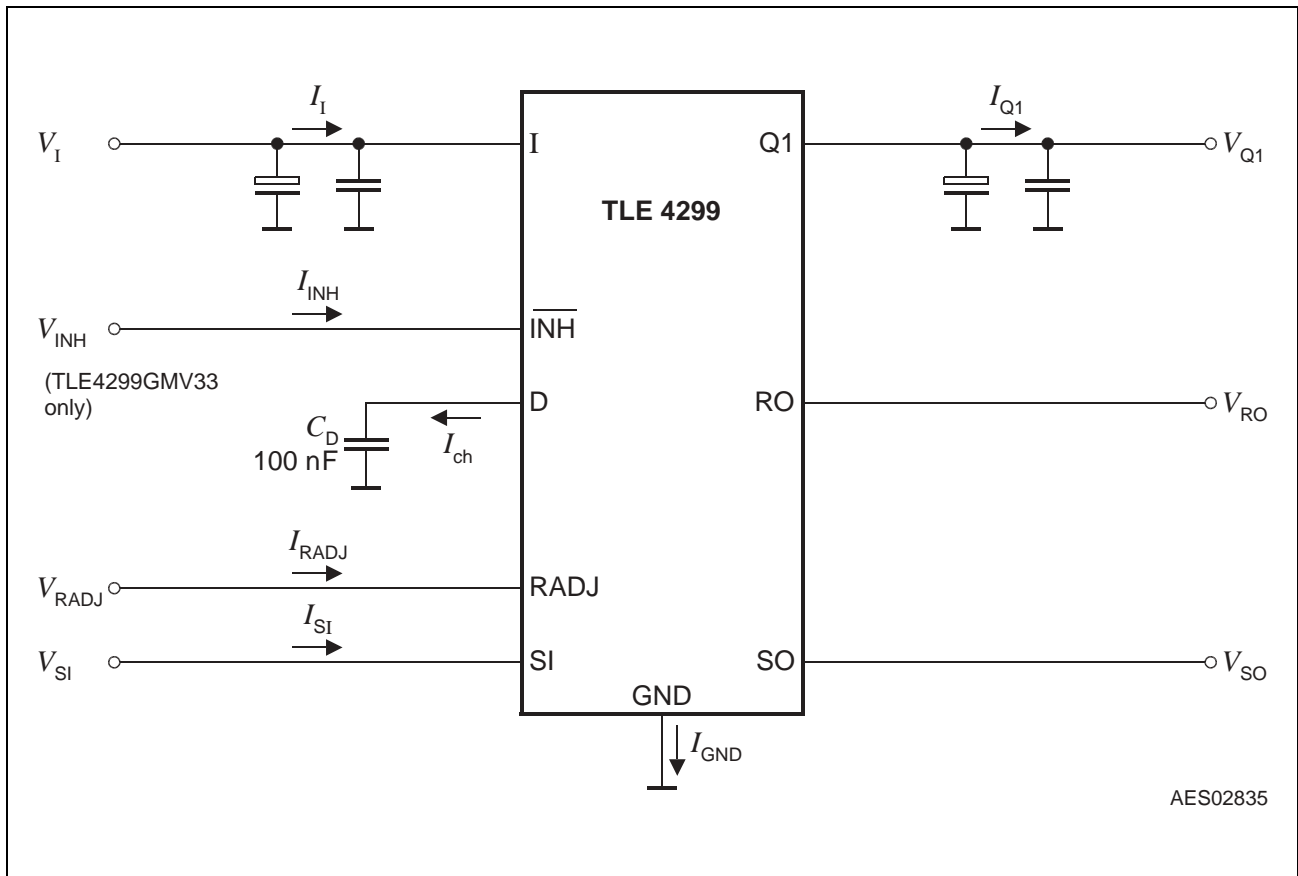

Figure 5 Measurement Circuit

Application Information

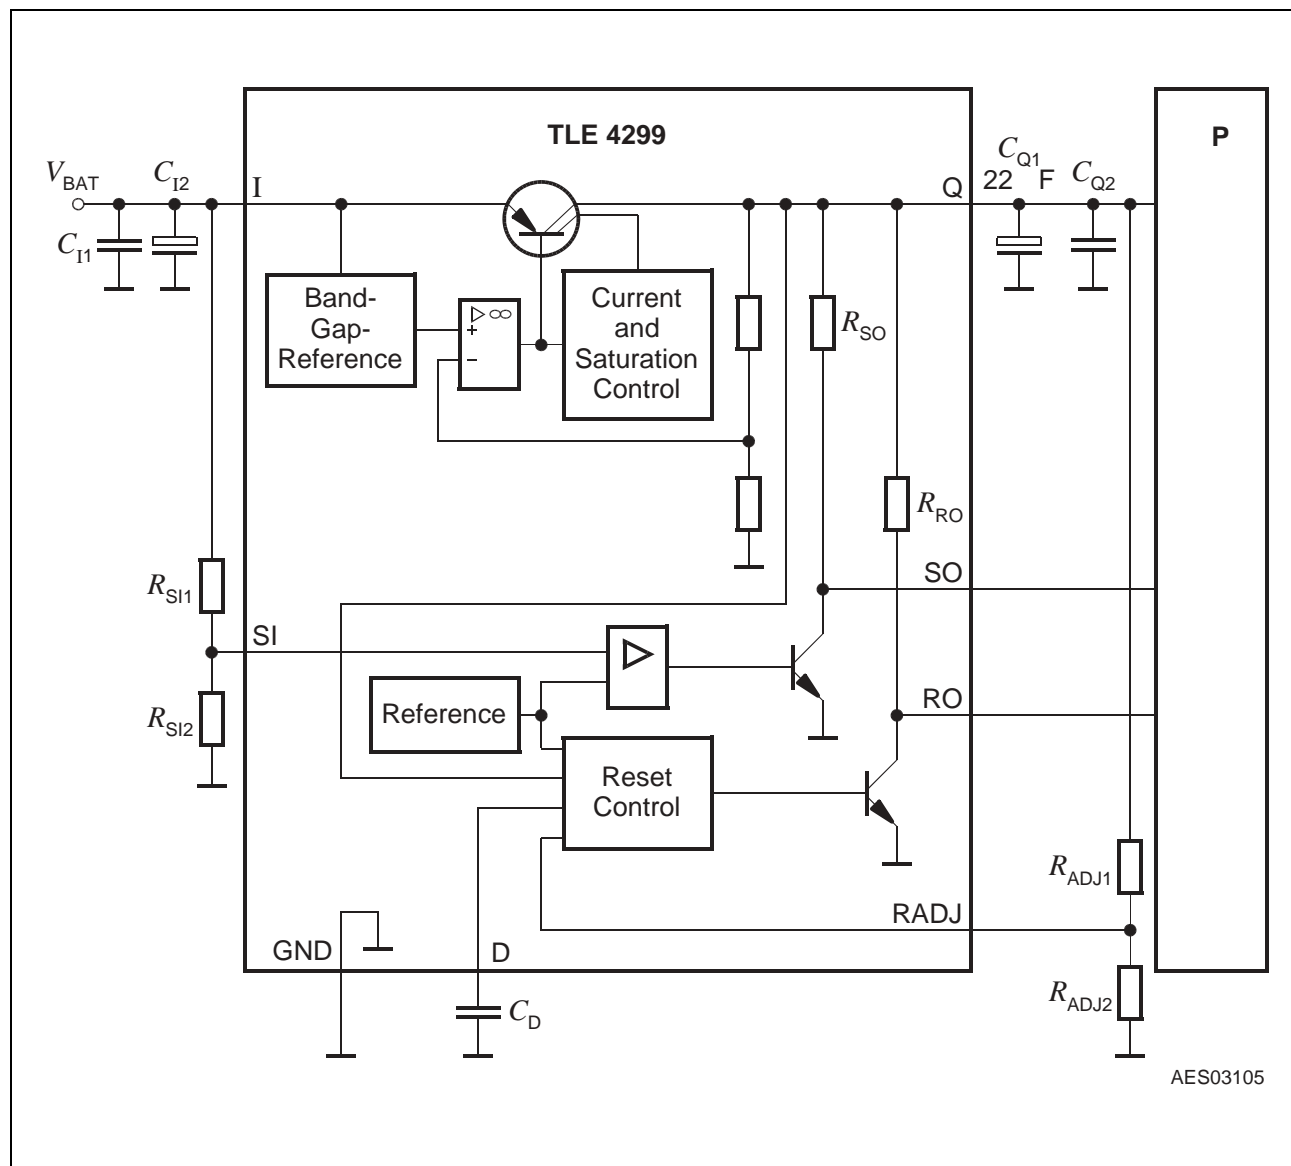

Figure 6 Application Diagram TLE 4299 GV33

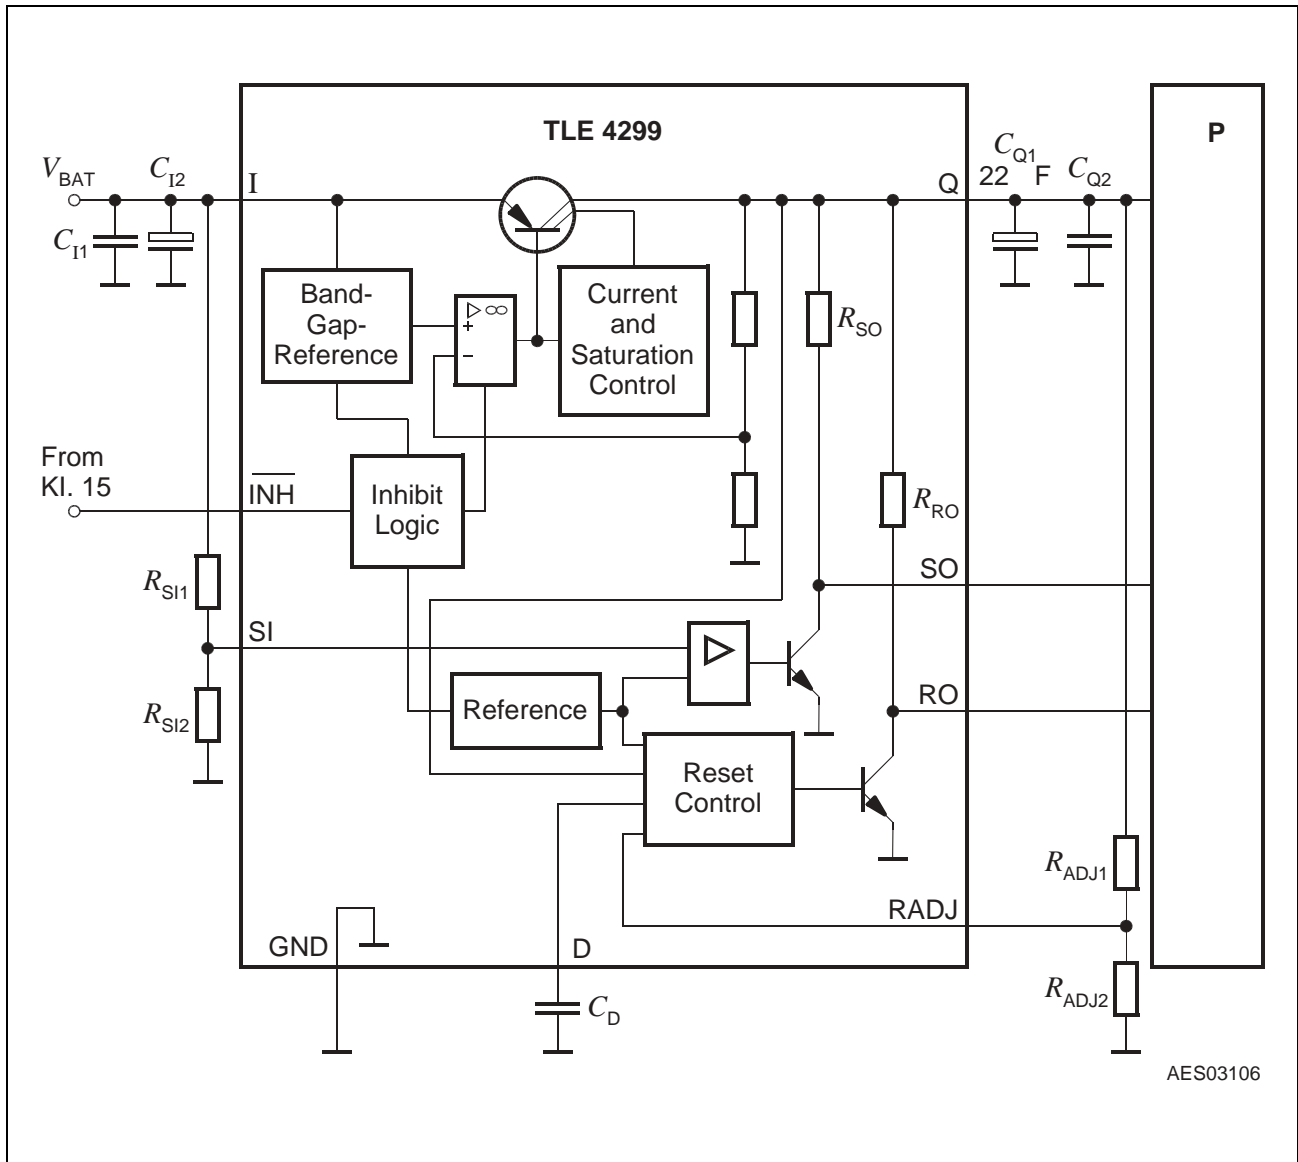

Figure 7 Application Diagram with Inhibit Function TLE4299 GMV33

The TLE 4299 supplies a regulated 3.3 V output voltage with an accuracy of 2% for an input voltage between 4.4 V and 45 V in the temperature range of $T_j = -40$ to 150 °C, in an output current range of 1 mA to 100 mA.

The device is capable to supply 150 mA with an accuracy of 3%. For protection at high input voltage above 25 V, the output current is reduced (SOA protection).

An input capacitor is necessary for compensating line influences and to limit steep input edges. A resistor of approx. 1Ω in series with C_I , can damp the LC of the input inductivity and the input capacitor.

The voltage regulator requires for stability an output capacitor C_Q of at least $22 \mu F$ with an $0.4 \Omega < ESR < 3.7 \Omega$ for the whole load- and temperature range. For more detailed information, refer to the characteristic curves.

Reset

The power on reset feature is necessary for a defined start of the microprocessor when switching on the application. For the reset delay time after the output voltage of the regulator is above the reset threshold, the reset signal is set High again. The reset delay time is defined by the reset delay capacitor C_D at pin D.

The under-voltage reset circuitry supervises the output voltage. In case V_Q decreases below the reset threshold the reset output is set LOW after the reset reaction time. The reset LOW signal is generated down to an output voltage V_Q to 1 V. Both the reset reaction time and the reset delay time is defined by the capacitor value.

The power on reset delay time is defined by the charging time of an external delay capacitor C_D .

$$C_D = (t_d \times I_D) / \Delta V \quad [1]$$

$$t_d = C_D \times \Delta V / I_D \quad [2]$$

With C_D reset delay capacitor
 t_d reset delay time
 $\Delta V = V_{DT}$, typical 1.8 V for power up reset
 I_{ch} charge current typical 3.5 μA

For a delay capacitor $C_D = 100$ nF the typical power on reset delay time is 51 ms.

The reset reaction time t_{RR} is the time it takes the voltage regulator to set reset output LOW after the output voltage has dropped below the reset threshold. It is typically 1.2 μs for delay capacitor of 100 nF. For other values for C_D the reaction time can be estimated using the following equation:

$$t_{RR} \sim 10 \text{ ns} / \text{nF} \times C_D \quad [3]$$

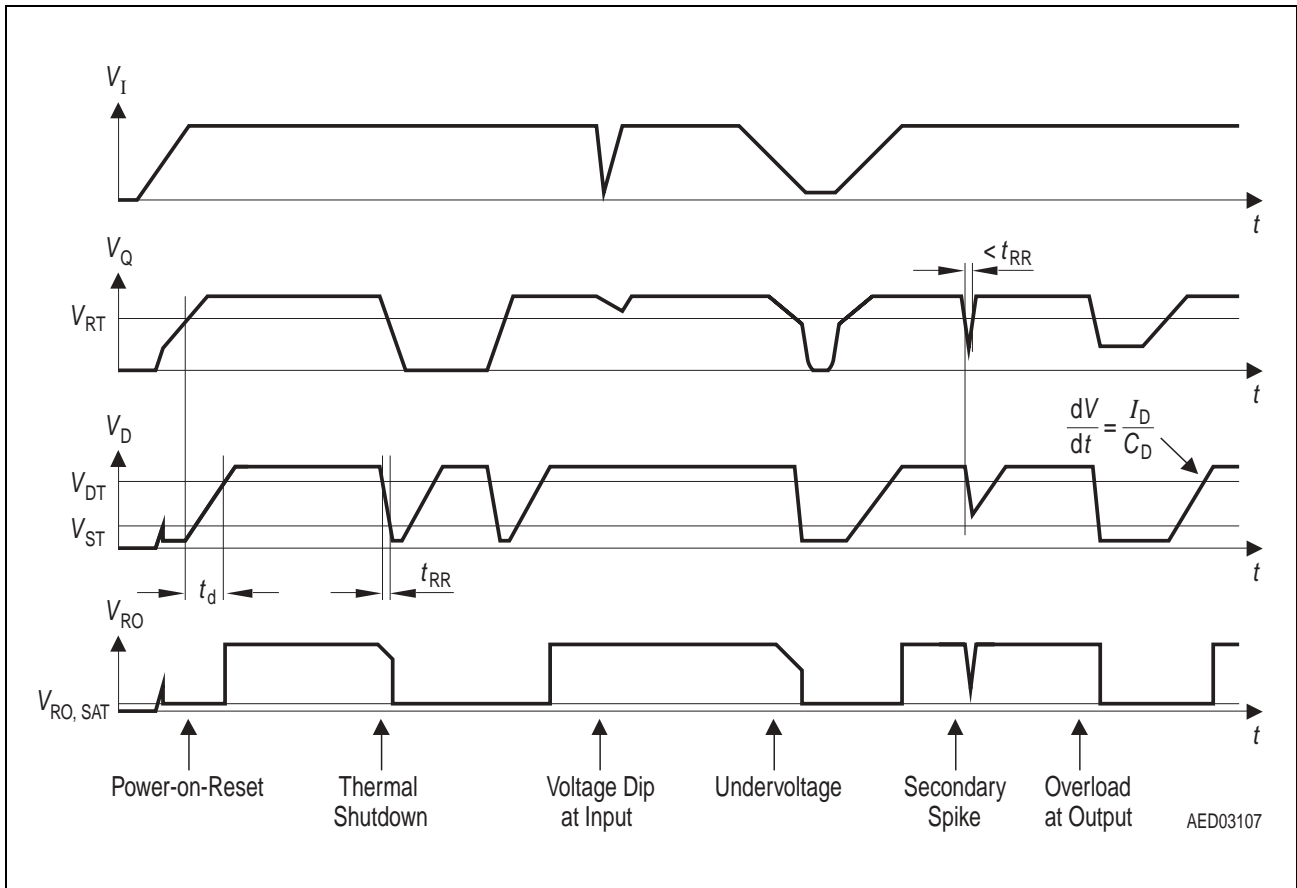

Figure 8 Reset Timing Diagram

The reset output is an open collector output. An external pull-up can be added with a resistor value of at least 5.6 k Ω .

In addition the reset switching threshold can be adjusted by an external voltage divider.

The feature is useful for microprocessors which guarantee safe operation down to voltages below the internally set reset threshold of 3.10V typical. If the internal used reset threshold of typical 3.10V is used, the pin RADJ has to be connected to GND.

If a lower reset threshold is required by the system, a voltage divider defines the reset threshold V_{Rth} between 2.5V and 3.10V as long as the Input Voltage $V_I > 4.4V$

$$V_{Rth} = V_{RADJ TH} * (R_{ADJ1} + R_{ADJ2}) / R_{ADJ2} \quad (3)$$

$V_{RADJ TH}$ is typical 1.36 V.

Early Warning

The early warning function compares a voltage defined by the user to an internal reference voltage. Therefore the supervised voltage has to be scaled down by an external voltage divider in order to compare it to the internal sense threshold of typical 1.36 V. The sense output pin is set low, when the voltage at SI falls below this threshold.

A typical example where the circuit can be used is to supervise the input voltage V_I to give the microcontroller a prewarning of low battery condition.

Calculation to the voltage divider can be easily done since the sense input current can be neglected.

Figure 9 **Sense Timing Diagram**

$$V_{thHL} = (R_{SI1} + R_{SI2})/R_{SI2} \times V_{SI\ low} \quad [4]$$

$$V_{thLH} = (R_{SI1} + R_{SI2})/R_{SI2} \times V_{SI\ high} \quad [5]$$

The sense in comparator uses a hysteresis of typical 90 mV. This hysteresis of the supervised threshold is multiplied by the resistor dividers amplification $(R_{SI1} + R_{SI2})/R_{SI1}$.

The sense in comparator can also be used for receiving data with a threshold of typical 1.36 V and a hysteresis of 90 mV. Of course also the data signal can be scaled down with a resistive divider as shown above. With a typical delay time of 2.5 μ s for positive transitions and 2.4 μ s for negative transitions receiving data of up to 100 kBaud are possible. The sense output is an open collector output.
