

# SL2309

## Low Jitter and Skew 10 to 140 MHz Zero Delay Buffer (ZDB)

### Key Features

- 10 to 140 MHz operating frequency range
- Low output clock skew: 50ps-typ
- Low output clock jitter:
  - 50 ps-typ cycle-to-cycle jitter
- Low part-to-part output skew: 150 ps-typ
- 3.3 V power supply range
- Low power dissipation:
  - 28 mA-max at 66 MHz
  - 44 mA -max at 140 MHz
- One input drives 9 outputs organized as 4+4+1
- Select mode to bypass PLL or tri-state outputs
- SpreadThru™ PLL that allows use of SSCG
- Standard and High-Drive options
- Available in 16-pin SOIC and TSSOP packages
- Available in Commercial and Industrial grades

### Applications

- Printers and MFPs
- Digital Copiers
- PCs and Work Stations
- DTV
- Routers, Switchers and Servers
- Digital Embedded Systems

### Description

The SL2309 is a low skew, low jitter and low power Zero Delay Buffer (ZDB) designed to produce up to nine (9) clock outputs from one (1) reference input clock, for high speed clock distribution applications.

The product has an on-chip PLL which locks to the input clock at CLKIN and receives its feedback internally from the CLKOUT pin.

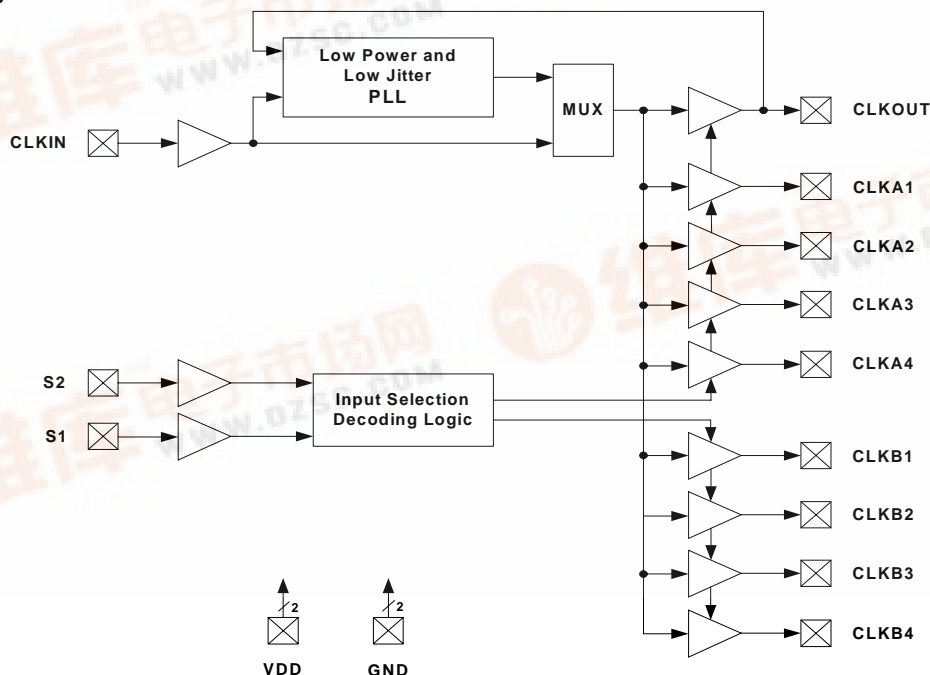

The SL2309 has two (2) clock driver banks each with four (4) clock outputs. These outputs are controlled by two (2) select input pins S1 and S2. When only four (4) outputs are needed, four (4) bank-B output clock buffers can be tri-stated to reduce power dissipation and jitter. The select inputs can also be used to tri-state both banks A and B or drive them directly from the input bypassing the PLL and making the product behave like a Non-Zero Delay Buffer (NZDB).

The high-drive (-1H) version operates up to 140MHz and low drive (-1) version operates up to 100MHz at 3.3V.

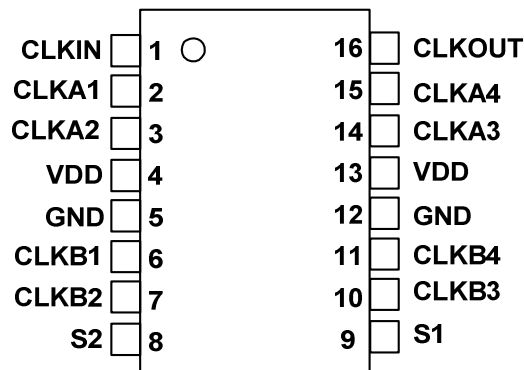

### Benefits

- Up to nine (9) distribution of input clock
- Standard and High-Drive levels to control impedance level, frequency range and EMI
- Low power dissipation, jitter and skew
- Low cost

### Block Diagram

## Pin Configuration

16-Pin SOIC and TSSOP

## Pin Description

Pin Number	Pin Name	Pin Type	Pin Description
1	CLKIN	Input	Reference Frequency Clock Input. Weak pull-down (250k $\Omega$ ).
2	CLKA1	Output	Buffered Clock Output, Bank A. Weak pull-down (250k $\Omega$ ).
3	CLKA2	Output	Buffered Clock Output, Bank A. Weak pull-down (250k $\Omega$ ).
4	VDD	Power	3.3V Power Supply.
5	GND	Power	Power Ground.
6	CLKB1	Output	Buffered Clock Output, Bank B. Weak pull-down (250k $\Omega$ ).
7	CLKB2	Output	Buffered Clock Output, Bank B. Weak pull-down (250k $\Omega$ ).
8	S2	Input	Select Input, select pin S2. Weak pull-up (250k $\Omega$ ).
9	S1	Input	Select Input, select pin S1. Weak pull-up (250k $\Omega$ ).
10	CLKB3	Output	Buffered Clock Output, Bank B. Weak pull-down (250k $\Omega$ ).
11	CLKB4	Output	Buffered Clock Output, Bank B. Weak pull-down (250k $\Omega$ ).
12	GND	Power	Power Ground.
13	VDD	Power	3.3V Power Supply.
14	CLKA3	Output	Buffered Clock Output, Bank A. Weak pull-down (250k $\Omega$ ).
15	CLKA4	Output	Buffered Clock Output, Bank A. Weak pull-down (250k $\Omega$ ).
16	CLKOUT	Output	Buffered Clock Output, PLL Internal Feedback Output. Weak pull-down (250k $\Omega$ ).

### General Description

The SL2309 is a low skew, low jitter Zero Delay Buffer with very low operating current.

The product includes an on-chip high performance PLL that locks into the input reference clock and produces nine (9) output clock drivers tracking the input reference clock for systems requiring clock distribution.

in addition to CLKOUT that is used for internal PLL feedback, there are two (2) banks with four (4) outputs in each bank, bringing the number of total available output clocks to nine (9).

### Input and Output Frequency Range

The input and output frequency range is the same. But, it depends on the drive and CL levels as given in the below Table 1.

Drive	CL(pF)	Min(MHz)	Max(MHz)
HIGH	15	10	140
HIGH	30	10	100
LOW	15	10	100
LOW	30	10	66

**Table 1. Input/Output Frequency Range**

If the input clock is DC (GND to VDD) or floating, this is detected by an input frequency detection circuitry and all nine (9) clock outputs are forced to Hi-Z. The PLL is shutdown to save power. In this shutdown state, the product draws less than 12µA-max supply current.

In PLL by-pass mode (S2=1 and S1=0), the detection circuit is disabled and input frequency range is 10 to 100MHz for standard (-1) drive and 10 to 140MHz for high (-1H) drive.

### SpreadThru™ Feature

If a Spread Spectrum Clock (SSC) were to be used as an input clock, the SL2309 is designed to pass the modulated Spread Spectrum Clock (SSC) signal from its reference input to the output clocks. The same spread characteristics at the input are passed through the PLL and drivers without any degradation in spread percent (%), spread profile and modulation frequency

### Select Input Control

The SL2309 provides two (2) input select control pins called S1 (Pin-9) and S2 (Pin-8). This feature enables users to select various states of output clock banks-A and bank-B, output source and PLL shutdown features as shown in the Table 2.

The S1 (Pin-9) and S2 (Pin-8) inputs include 250 kΩ weak pull-up resistors to VDD.

### PLL Bypass Mode

If the S1 and S2 pins are logic Low(0) and High(1) respectively, the on-chip PLL is shutdown and bypassed, and all the nine output clocks bank A, bank B and CLKOUT clocks are driven by directly from the reference input clock. In this operation mode SL2309 works like a non-ZDB fanout buffer. In this operation mode the input power-down detection circuit is disabled and outputs follow the input clock from DC to rated frequencies based on drive levels and load specifications.

### High and Low-Drive Product Options

The SL2309 is offered with High Drive “-1H” and Standard Drive “-1” options. These drive options enable the users to control load levels, frequency range and EMI. Refer to the switching electrical tables for the details.

### Skew and Zero Delay

All outputs should drive the similar load to achieve the output-to-output skew and input-to-output specifications given in the switching electrical tables. However, Zero Delay between input and outputs can be adjusted by changing the loading at CLKOUT relative to the banks A and B clocks since CLKOUT is the feedback to the PLL.

### Power Supply Range (VDD)

The SL2309 is designed to operate at VDD=3.3V (+/-10%). An internal on-chip voltage regulator is used to provide PLL constant power supply of 1.8V, leading to a consistent and stable PLL electrical performance in terms of skew, jitter and power dissipation.

Refer to SL23EP09 for 3.3V to 2.5V and SL23EPL09 for 1.8V power supply operations.

S2	S1	Clock A1-A4	Clock B1-4	CLKOUT	Output Source	PLL Status
0	0	Tri-state	Tri-state	Driven	PLL	On
0	1	Driven	Tri-state	Driven	PLL	On
1	0	Driven	Driven	Driven	Reference	Off
1	1	Driven	Driven	Driven	PLL	On

**Notes:**

1. For the given maximum loading conditions. See CL in Operating Conditions Table.
2. Parameter is guaranteed by design and characterization. Not 100% tested in production.

## External Components & Design Considerations

### Typical Application Schematic

### Comments and Recommendations

**Decoupling Capacitor:** A decoupling capacitor of 0.1µF must be used between VDD and VSS pins. Place the capacitor s on the component side of the PCB as close to the VDD pins as possible. The PCB trace to the VDD pin and to the GND via should be kept as short as possible. Do not use vias between the decoupling capacitor and the VDD pin.

**Series Termination Resistor:** A series termination resistor is recommended if the distance between the output clocks and the load is over 1 ½ inch. The nominal impedance of the clock outputs is given on the page 4. Place the series termination resistors as close to the clock outputs as possible.

**Zero Delay and Skew Control:** All outputs and CLKIN pins should be loaded with the same load to achieve “Zero Delay” between the CLKIN and the outputs. The CLKOUT pin is connected to CLKIN internally on-chip for feedback to PLL, and sees an additional 2 pF load with respect to Bank A and B clocks. For applications requiring zero input/output delay, the load at the all output pins including the CLKOUT pin must be the same. If any delay adjustment is required, the capacitance at the CLKOUT pin could be increased or decreased to increase or decrease the delay between Bank A and B clocks and CLKIN.

For minimum pin-to-pin skew, the external load at all the Bank A and B clocks must be the same.
