19-2531: Rev 1: 4/03

MVXVN Low-Power Dual-/Triple-Voltage SC70 µP **Supervisory Circuits**

General Description

The MAX6736-MAX6745 are low-power dual-/triplevoltage microprocessor (µP) supervisors. These devices assert a reset if any monitored supply falls below its factory-trimmed or adjustable threshold and maintain reset for a minimum timeout period after all supplies rise above their thresholds. The integrated dual/triple supervisory circuits significantly reduce size and power compared to separate ICs or discrete components. The low supply current of 6µA makes these devices ideal for portable equipment.

The MAX6736/MAX6737 are dual fixed-voltage µP supervisors with a manual reset input. The MAX6738/ MAX6739 have one fixed and one adjustable reset threshold and a manual reset input. The MAX6740/ MAX6743 are triple-voltage µP supervisors with two fixed and one user-adjustable reset threshold inputs. The MAX6741/MAX6744 are dual-voltage µP supervisors with a power-OK (POK) output ideal for powersupply sequencing. The MAX6742/MAX6745 monitor the primary VCC supply and have an independent power-fail comparator.

The MAX6736–MAX6745 monitor I/O supply voltages (V_{CC}1) from 1.8V to 5.0V and core supply voltages (V_{CC}2) from 0.9V to 3.3V with factory-trimmed reset threshold voltage options (Table 1). An external adjustable RSTIN input option allows monitoring voltages down to 0.5V.

A variety of push-pull or open-drain reset outputs along with manual reset input and power-fail input/output features are available (see the Selector Guide). The MAX6736-MAX6745 are offered in a space-saving 5-pin SC70 package and operate over the -40°C to +85°C temperature range.

Features

Dual-/Triple-Supply Reset Voltage Monitors

捷多邦,专业PCB打样工厂,24小时加急出货

- Precision Factory-Set Reset Thresholds for Monitoring from 0.9V to 5.0V
- Adjustable Reset Input Down to 0.488V
- 150ms and 1200ms (min) Reset Timeout Period Options
- Vcc1 Power-OK Output for Power-Supply Sequencing Applications (MAX6741/MAX6744)
- Power-Fail Input/Power-Fail Output WWW.0ZSC. (MAX6742/MAX6745)
- 6µA Supply Current
- Tiny SC70 Package

Ordering Information

PART	TEMP RANGE	PIN-PACKAGE
MAX6736XKDT	-40°C to +85°C	5 SC70-5
MAX6737XKDT	-40°C to +85°C	5 SC70-5

Note: The first "__" or "_" are placeholders for the threshold voltage levels of the devices. Desired threshold levels are set by the part number suffix found in Tables 1 and 2. The "_" after the D is a placeholder for the reset timeout period suffix found in Table 3. For example, the MAX6736XKLTD3-T is a dual-voltage supervisor $V_{TH}1 = 4.625V$, $V_{TH}2 = 3.075V$, and a 150ms minimum reset timeout period. All devices are available in tape-and-reel only. There is a 2500-piece minimum order increment for standard versions (see Table 1). Sample stock is typically held on standard versions only. Nonstandard versions require a minimum order increment of 10,000 pieces. Contact factory for availability.

Ordering Information continued at end of data sheet. Selector Guide continued at end of data sheet. Pin Configurations appear at end of data sheet. Typical Application Circuits appear at end of data sheet. Functional Diagram appears at end of data sheet.

ABSOLUTE MAXIMUM RATINGS

VCC1, VCC2, POK1 to GND	
Open-Drain RESET, PFO to GND	0.3V to +6V
Push-Pull RESET to GND	0.3V to (V _{CC} 1 + 0.3V)
MR, RSTIN, PFI to GND	0.3V to (V _{CC} 1 + 0.3V)
Input/Output Current, All Pins	
Continuous Power Dissipation (T _A =	+70°C)
5-Pin SC70 (derate 3.1mW/°C abo	ove +70°C)247mW

Operating Temperature Range	40°C to +85°C
Junction Temperature	
Storage Temperature Range	
Lead Temperature (soldering, 10s)	+300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

 $(V_{CC} = 1.2V \text{ to } 5.5V, T_A = -40^{\circ}C \text{ to } +85^{\circ}C, \text{ unless otherwise noted. Typical values are at T_A = +25^{\circ}C.)$ (Note 1)

Pin Description

		PIN				
MAX6736 MAX6737	MAX6738 MAX6739	MAX6740 MAX6743	MAX6741 MAX6744	MAX6742 MAX6745	NAME	FUNCTION
1	1	1	1	1	RESET	Reset Output, Push-Pull or Open Drain Active Low. RESET changes from high to low when any monitored power-supply input (V _{CC} 1, V _{CC} 2, RSTIN) drops below its selected reset threshold. It remains low until all monitored power-supply inputs exceed their selected reset thresholds for the V _{CC} reset timeout period. RESET is forced low if MR is low for at least the MR minimum input pulse width. It remains low for the MR reset timeout period after MR goes high. The push-pull output is referenced to V _{CC} 1. The MAX6736/MAX6738 open-drain outputs require an external pullup resistor. The MAX6740/MAX6741/MAX6742 open-drain outputs have an internal 50k Ω pullup resistor to V _{CC} 1 and provide a manual reset function.
2	2	2	2	2	GND	Ground
3	3				MR	Manual Reset, Active Low. Pull low for at least $\overline{\text{MR}}$ minimum input pulse width to force $\overline{\text{RESET}}$ low. Reset remains active as long as $\overline{\text{MR}}$ is low and for the $\overline{\text{MR}}$ reset timeout period after $\overline{\text{MR}}$ goes high. There is an internal 1.5k Ω pullup resistor to V _{CC} 1.
4	_	4	4	—	V _{CC} 2	Voltage Input 1. Power supply and input for the secondary μP voltage reset monitor.
_	4	3			RSTIN	Adjustable Reset Threshold Input. $\overrightarrow{\text{RESET}}$ is asserted when RSTIN is below the internal 0.488V reference level. Set the adjustable reset threshold with an external resistor-divider network. Connect RSTIN to V _{CC} 1 if unused.
5	5	5	5	5	V _{CC} 1	Voltage Input 2. Power supply and input for the primary μP voltage reset monitor.
_				4	PFI	Power-Fail Comparator Input. PFO is asserted when PFI is below 0.488V. PFO is deasserted without any reset timeout period when PFI goes above 0.488V. Connect PFI to an external resistor network to set the desired monitor threshold.
_				3	PFO	Power-Fail Comparator Output, Open Drain Active Low. PFO is asserted when PFI is below 0.488V.
_	_	—	3	_	POK1	$V_{CC}1$ Power-OK Output, Open Drain Active High. POK1 remains low as long as $V_{CC}1$ is below $V_{TH}1$. POK1 output goes high after $V_{CC}1$ exceeds $V_{TH}1$ for the POK1 timeout period. POK1 logic is independent of the \overline{MR} or $V_{CC}2$ inputs. The output can be used to control $V_{CC}1$ -to- $V_{CC}2$ supply sequencing.

MAX6736-MAX6745

Detailed Description

Supply Voltages

The MAX6736–MAX6745 μP supervisory circuits maintain system integrity by alerting the μP to fault conditions. These devices are optimized for systems that monitor two or three supply voltages. The reset output state is guaranteed to remain valid while either V_{CC}1 or V_{CC}2 is above 1.2V.

Threshold Levels

The MAX6736/MAX6737/MAX6740/MAX6741/MAX6743/ MAX6744 input voltage threshold combinations are indicated by a two-letter code in Table 1. The MAX6738/ MAX6739/MAX6742/MAX6745 input voltage thresholds are indicated by a one-letter code in Table 2. Contact the factory for the availability of other voltage thresholds.

Reset Output

The MAX6736–MAX6745 provide an active-low reset output (RESET). RESET is asserted when the voltage at either V_{CC}1 or V_{CC}2 falls below the voltage threshold level, RSTIN drops below the threshold, or MR is pulled low. Once reset is asserted, it stays low for the reset time-out period. If V_{CC}1, V_{CC}2, or RSTIN goes below the reset threshold before the reset timeout period is completed, the internal timer restarts. The MAX6736/MAX6738/MAX6740/MAX6741/MAX6742 have open-drain reset outputs, while the MAX6737/MAX6739/MAX6743/MAX6744/MAX6745 have push-pull reset outputs (Figure 1).

The MAX6740/MAX6741/MAX6742 include a $\overline{\text{RESET}}$ output with a manual reset detect function. The opendrain $\overline{\text{RESET}}$ output has an internal 50k Ω pullup to V_{CC1}. The RESET output is low while the output is pulled to GND and remains low for at least the manual reset timeout period after the external GND pulldown is

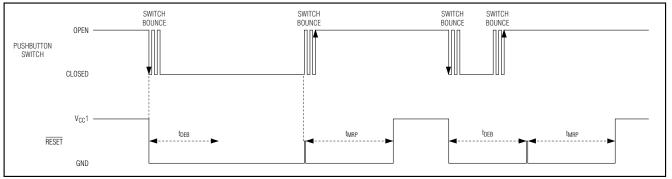

Figure 2. MAX6740/MAX6741/MAX6742 Manual Reset Timing Diagram

released. The manual reset detect function is internally debounced for the t_{DEB} timeout period, so the output can be connected directly to a momentary pushbutton switch, if desired (Figure 2).

Manual Reset Input

Many microprocessor-based products require manual reset capability, allowing the operator, a test technician, or external logic circuitry to initiate a reset while the monitored supplies remain above their reset thresholds. The MAX6736–MAX6739 have a dedicated active-low MR input. The RESET is asserted low while MR is held low and remains asserted for the manual reset timeout period after MR returns high. The MR input has an internal 1.5k Ω pullup resistor to Vcc1 and can be left unconnected if not used. MR can be driven with CMOS logic levels, open-drain/open-collector outputs, or a momentary pushbutton switch to GND to create a manual reset function.

Adjustable Input Voltage

The MAX6738/MAX6739 and MAX6740/MAX6743 provide an additional input to monitor a second or third system voltage. The threshold voltage at RSTIN is typi-

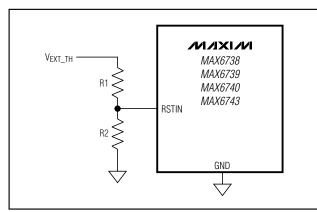

Figure 3. Monitoring an Additional Voltage

cally 488mV. Connect a resistor-divider network to the circuit as shown in Figure 3 to establish an externally controlled threshold voltage, V_{EXT_TH}.

$$V_{EXT}$$
 TH = 0.488V((R1 + R2) / R2)

Low leakage current at RSTIN allows the use of largevalued resistors, resulting in reduced power consumption of the system.

Power-Fail Comparator

PFI is the noninverting input to an auxiliary comparator. A 488mV internal reference (V_{TH}-P_{FI}) is connected to the inverting input of the comparator. If PFI is less than 488mV, PFO is asserted low. PFO deasserts without a timeout period when PFI rises above the externally set threshold. Common uses for the power-fail comparator include monitoring for low battery conditions or a failing DC-DC converter input voltage (see the *Typical Application Circuits*). The asserted PFO output can place a system in a low-power suspend mode or support an orderly system shutdown before monitored V_{CC} voltages drop below the reset thresholds. Connect PFI to an external resistor-divider network as shown in Figure 4 to set the desired trip threshold. Connect PFI to V_{CC}1 if unused.

Applications Information

Interfacing to the µP with Bidirectional Reset Pins

Most microprocessors with bidirectional reset pins can interface directly to open-drain RESET output options. Systems simultaneously requiring a push-pull RESET output and a bidirectional reset interface can be in logic contention. To prevent contention, connect a 4.7k Ω resistor between RESET and the μ P's reset I/O port as shown in Figure 5.

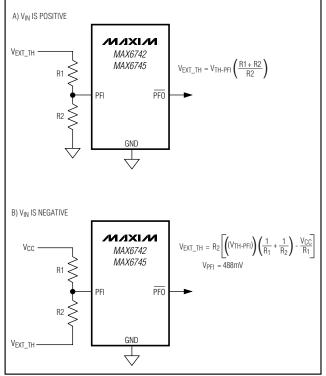

Figure 4. Using Power-Fail Input to Monitor an Additional Power Supply

Adding Hysteresis to the Power-Fail Comparator

The power-fail comparator has a typical input hysteresis of 2.5mV. This is sufficient for most applications in which a power-supply line is being monitored through an external voltage-divider. If additional noise margin is desired, connect a resistor between PFO and PFI, as

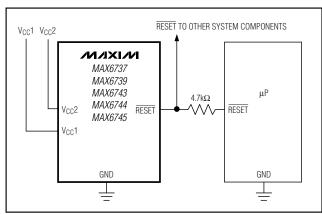

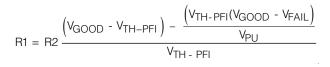

Figure 5. Interfacing to µPs with Bidirectional Reset I/O

shown in Figure 6. Select the values of R1, R2, and R3 such that PFI sees V_{TH-PFI} (488mV) when V_{EXT} falls to its power-fail trip point (V_{FAIL}) and when V_{EXT} rises to its power-good trip point (V_{GOOD}). The hysteresis window extends between the specified V_{FAIL} and V_{GOOD} thresholds. R3 adds the additional hysteresis by sinking current from the R1/R2 divider network when the PFO output is logic low and sourcing current into the network when PFO is logic high. R3 is typically an order of magnitude greater than R1 or R2.

The current through R2 should be at least 1μ A to ensure that the 10nA (max) PFI input current does not significantly shift the trip points. Therefore, for most applications:

 $\label{eq:response} \begin{array}{l} R2 < V_{TH-PFI} \ / \ 1mA < 0.488V \ / \ 1mA < 488k\Omega \\ \hline \hline PFO \ is an open-drain output requiring an external pullup resistor, R4. Select R4 to be less than 1% of R3. \\ \hline V_{GOOD} = DESIRED \ V_{EXT} \ GOOD \ VOLTAGE \ THRESHOLD \\ \hline V_{FAIL} = DESIRED \ V_{EXT} \ FAIL \ VOLTAGE \ THRESHOLD \\ \hline V_{PU} = \ V_{PULLUP} \ (FOR \ OPEN-DRAIN \ \overline{PFO}) \\ \hline R2 = 488k\Omega \ (FOR > 1\muA \ R2 \ CURRENT) \end{array}$

 $R3 = (R1 \times V_{PU}) / (V_{GOOD} - V_{FAIL})$ $R4 \le 0.01 \times R3$

Power Sequencing Applications

Many dual-voltage processors/ASICs require specific power-up/power-down sequences for the I/O and core supplies.

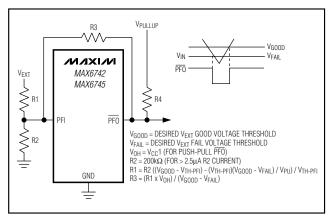

Figure 6. Adding Hysteresis to Power Fail for Push-Pull PFO

The MAX6741/MAX6744 offer a V_{CC1} POK (POK1) ideal for V_{CC1}-to-V_{CC2} sequencing. POK1 remains low as long as V_{CC1} is below its V_{TH1} threshold. When V_{CC1} exceeds V_{TH1} for the POK1 timeout period (t_{POKP}), the open-drain POK1 output is deasserted. The POK1 output can then enable the V_{CC2} power supply (use an external POK1 pullup resistor). RESET is deasserted when both V_{CC1} and V_{CC2} remain above their selected thresholds for the reset timeout period (t_{RP}). The POK1 output can be used for I/O before core or core before I/O sequencing, depending on the selected V_{CC1}/V_{CC2} thresholds. See the *Typical Application Circuit* and Figure 1.

Monitoring a Negative Voltage

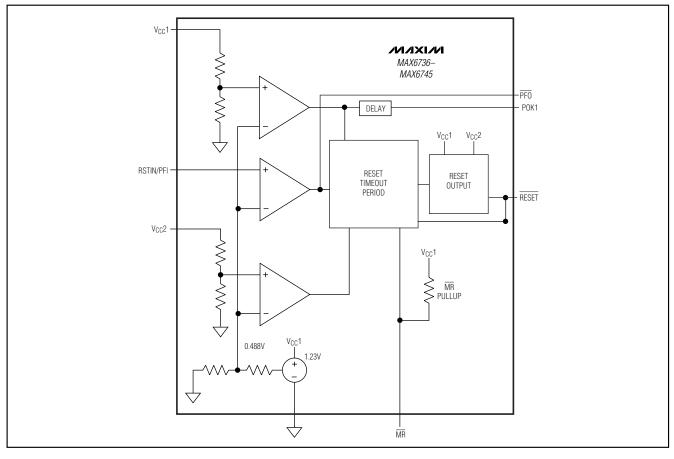

The power-fail comparator can be used to monitor a negative supply voltage using the circuit shown in Figure 4. When the negative supply is valid, <u>PFO</u> is low. When the negative supply voltage drops, <u>PFO</u> goes high. The circuit's accuracy is affected by the PFI threshold tolerance, V_{CC}, R1, and R2.

Transient Immunity

The MAX6736–MAX6745 supervisors are relatively immune to short-duration falling V_{CC} transients (glitches). It is usually undesirable to reset the μ P when V_{CC} experiences only small glitches. The *Typical Operating Characteristics* show Maximum V_{CC}1/V_{CC}2 Transient Duration vs. Reset Threshold Overdrive, for which reset pulses are not generated. The graph shows the maximum pulse width that a falling V_{CC} transient might typically have without causing a reset pulse to be issued. As the amplitude of the transient increases, the maximum allowable pulse width decreases. A 0.1µF bypass capacitor mounted close to the V_{CC} pin provides additional transient immunity.
