32-bit RISC Microprocessor - TX19 Family TMP19A64C1DXBG

1. Overview and Features

The TX19 family is a high-performance 32-bit RISC processor series that TOSHIBA originally developed by integrating the MIPS16TMASE (Application Specific Extension), which is an extended instruction set of high code efficiency.

TMP19A64 is a 32-bit RISC microprocessor with a TX19A processor core and various peripheral functions integrated into one package. It can operate at low voltage with low power consumption.

Features of TMP19A64 are as follows:

- (1) TX19A processor core
 - 1) Improved code efficiency and operating performance have been realized through the use of two ISA (Instruction Set Architecture) modes 16- and 32-bit ISA modes.
 - The 16-bit ISA mode instructions are compatible with the MIPS16e-TX instructions of superior code efficiency at the object level.
 - The 32-bit ISA mode instructions are compatible with the TX39 instructions of superior operating performance at the object level.
 - 2) Both high performance and low power consumption have been achieved.

RESTRICTIONS ON PRODUCT USE

070122EBP

- The information contained herein is subject to change without notice. 021023_D
- TOSHIBA is continually working to improve the quality and reliability of its products. Nevertheless, semiconductor devices in general can malfunction or fail due to their inherent electrical sensitivity and vulnerability to physical stress. It is the responsibility of the buyer, when utilizing TOSHIBA products, to comply with the standards of safety in making a safe design for the entire system, and to avoid situations in which a malfunction or failure of such TOSHIBA products could cause loss of human life, bodily injury or damage to property.

In developing your designs, please ensure that TOSHIBA products are used within specified operating ranges as set forth in the most recent TOSHIBA products specifications. Also, please keep in mind the precautions and conditions set forth in the "Handling Guide for Semiconductor Devices," or "TOSHIBA Semiconductor Reliability Handbook" etc. 021023_A

- The TOSHIBA products listed in this document are intended for usage in general electronics applications (computer, personal equipment, office equipment, measuring equipment, industrial robotics, domestic appliances, etc.). These TOSHIBA products are neither intended nor warranted for usage in equipment that requires extraordinarily high quality and/or reliability or a malfunction or failure of which may cause loss of human life or bodily injury ("Unintended Usage"). Unintended Usage include atomic energy control instruments, airplane or spaceship instruments, transportation instruments, traffic signal instruments, combustion control instruments, medical instruments, all types of safety devices, etc. Unintended Usage of TOSHIBA products listed in this document shall be made at the customer's own risk. 021023_B
- The products described in this document shall not be used or embedded to any downstream products of which manufacture, use and/or sale are prohibited under any applicable laws and regulations. 060106_Q
- The information contained herein is presented only as a guide for the applications of our products. No responsibility is assumed by TOSHIBA for any infringements of patents or other rights of the third parties which may result from its use. No license is granted by implication or otherwise under any patents or other rights of TOSHIBA or the third parties. 070122_C
- The products described in this document are subject to foreign exchange and foreign trade control laws. 060925_E
- For a discussion of how the reliability of microcontrollers can be predicted, please refer to Section 1.3 of the chapter entitled Quality and Reliability Assurance/Handling Precautions. 030619_S

- High performance
 - Almost all instructions can be executed with one clock.
 - High performance is possible via a three-operand operation instruction.
 - 5-stage pipeline
 - Built-in high-speed memory
 - DSP function: A 32-bit multiplication and accumulation operation can be executed with one clock.
- Low power consumption
 - Optimized design using a low power consumption library
 - Standby function that stops the operation of the processor core
- 3) High-speed interrupt response suitable for real-time control
 - Independency of the entry address
 - Automatic generation of factor-specific vector addresses
 - Automatic update of interrupt mask levels
- (2) On Chip program memory and data memory

Product name	On chip ROM	On chip RAM
TMP19A64F20AXBG	2 Mbytes (Flash)	64 Kbytes
TMP19A64C1DXBG	1.5 Mbytes	56 Kbytes

- ROM correction function: 1 word × 8 blocks, 8 words × 4 blocks
- Backup RAM: 512 bytes
- (3) External memory expansion
 - 16-Mbyte off-chip address for code and date
 - External data bus: Separate bus/multiplexed bus
 : Dynamic bus sizing for 8- and 16-bit widths ports.
 - Chip select/wait controller : 6 channels
- (4) DMA controller
 - Data to be transferred to internal memory, internal I/O, external memory, and external I/O
- (5) 16-bit timer
 - 16-bit interval timer mode
 - 16-bit event counter mode
 - 16-bit PPG output
 - Event capture function
 - 2-phase pulse input counter function (1 channel assigned to perform this function): Multiplication-by-4 mode
- (6) 32-bit timer
 - 32-bit input capture register : 4 channels
 - 32-bit compare register : 10 channels
 - 32-bit time base timer : 1 channel
- (7) Clock timer
- (8) General-purpose serial interface: 7 channels
 - Either UART mode or synchronous mode can be selected.

: 11 channels

: 1 channel

: 8 channels

- (9) Serial bus interface : 1 channel
 - Either I²C bus mode or clock synchronous mode can be selected
- (10) 10-bit A/D converter with (S/H)
 - Conversion speed: 54 clocks (7.85 µs@54 MHz)
 - Start by an internal timer trigger
 - Fixed channel/scan mode
 - Single/repeat mode
 - High-priority conversion mode
 - Timer monitor function
 - (11) Watchdog timer : 1 channel
 - (12) Interrupt source
 - CPU: 2 factors software interrupt instruction
 - Internal: 50 factors...... The order of precedence can be set over 7 levels (except the watchdog timer interrupt).
 - External: 20 factors...... The order of precedence can be set over 7 levels
 (except the NMI interrupt).
 Because 8 factors are associated with KWUP, the number of interrupt
 factors is one.

: 24 channels

- (13) 209 pins Input/output ports
- (14) Standby mode
 - 4 standby modes (IDLE, SLEEP, STOP and BACKUP)
- (15) Clock generator
 - On-chip PLL (multiplication by 4)
 - Clock gear function: The high-speed clock can be divided into 8/8, 7/8, 6/8, 5/8, 4/8, 2/8 or 1/8.
 - Sub-clock: SLOW, SLEEP and BACKUP modes (32.768 kHz)
- (16) Endian: Bi-endian (big-endian/little-endian)
- (17) Maximum operating frequency
 - 54 MHz (PLL multiplication)
- (18) Operating voltage range

Core: 1.35 V to 1.65 V

I/O: 1.65 V to 3.3 V

```
ADC: 2.7 V to 3.3 V
```

Backup block : 2.3 V to 3.3 V (under normal operating conditions) : 1.8 V to 3.3 V (in BACKUP mode)

- (19) Package
 - P-FBGA281 (13 mm × 13 mm, 0.65 mm pitch)

Table 2.1.1 Pin Numbers and Names (2 of 2)

#### 2.2 Pin Names and Functions

Table 2.2.1 shows the names and functions of input/output pins.

Pin name	Number of pins	Input or output	Function
P00-P07	8	Input/output	Port 0: Input/output port that allows input/output to be set in units of bits
D0-D7		Input/output	Data (lower): Data buses 0 to 7 (separate bus mode)
AD0-AD7		Input/output	Address data (lower): Address data buses 0 to 7 (multiplexed bus mode)
P10-P17	8	Input/output	Port 1: Input/output port that allows input/output to be set in units of bits
D8-D15		Input/output	Data (upper): Data buses 8 to 15 (separate bus mode)
AD8-AD15		Input/output	Address data (upper): Address data buses 8 to 15 (multiplexed bus mode)
A8-A15		Output	Address: Address buses 8 to 15 (multiplexed bus mode)
P20-P27	8	Input/output	Port 2: Input/output port that allows input/output to be set in units of bits
A16-A23		Output	Address: Address buses 16 to 23 (separate bus mode)
A0-A7		Output	Address: Address buses 0 to 7 (multiplexed bus mode)
A16-A23		Output	Address: Address buses 16 to 23 (multiplexed bus mode)
P30	1	Output	Port 30: Port used exclusively for output
RD		Output	Read: Strobe signal for reading external memory
P31	1	Output	Port 31: Port used exclusively for output
WR		Output	Write: Strobe signal for writing data of D0 to D7 pins
P32	1	Input/output	Port 32: Input/output port (with pull-up)
HWR		Output	Write upper-pin data: Strobe signal for writing data of D8 to D15 pins
P33	1	Input/output	Port 33: Input/output port (with pull-up)
WAIT	1	Input	Wait: Pin for requesting CPU to put a bus in a wait state
RDY		Input	Ready: Pin for notifying CPU that a bus is ready
P34	1	Input/output	Port 34: Input/output port (with pull-up)
BUSRQ	1		Bus request: Signal requesting CPU to allow an external master to take the bus control authority
	1	Input	Port 35: Input/output port (with pull-up)
P35 BUSAK	1	Input/output	
DUSAK		Output	Bus acknowledge: Signal notifying that CPU has released the bus control authority in response to BUSRQ
P36	1	Input/output	Port 36: Input/output port (with pull-up)
R/W		Output	Read/write: "1" shows a read cycle or a dummy cycle. "0" shows a write cycle.
P37	1	Input/output	Port 37: Input/output port
ALE		Output	Address latch enable (address latch is enabled only if access to external memory is taking place)
P40	1	Input/output	Port 40: Input/output port (with pull-up)
CS0		Output	Chip select 0: "0" is output if the address is in a designated address area.
P41	1	Input/output	Port 41: Input/output port (with pull-up)
CS1		Output	Chip select 1: "0" is output if the address is in a designated address area.
P42	1	Input/output	Port 42: Input/output port (with pull-up)
CS2		Output	Chip select 2: "0" is output if the address is in a designated address area.
P43	1	Input/output	Port 43: Input/output port (with pull-up)
CS3		Output	Chip select 3: "0" is output if the address is in a designated address area.
P44	1	Input/output	Port 44: Input/output port (with pull-up)
CS4		Output	Chip select 4: "0" is output if the address is in a designated address area.
P45	1	Input/output	Port 45: Input/output port (with pull-up)
CS5	-	Output	Chip select 5: "0" is output if the address is in a designated address area.
P46	1	Input/output	Port 46: Input/output port
SCOUT		Output	System clock output: Selectable between high- and low-speed clock outputs, as in the case of
		-	CPU
P47	1	Input/output	Port 47: Input/output port
P50-P57	8	Input/output	Port 5: Input/output port that allows input/output to be set in units of bits
A0-A7		Output	Address: Address buses 0 to 7 (separate bus mode)
P60-P67	8	Input/output	Port 6: Input/output port that allows input/output to be set in units of bits
A8-A15		Output	Address: Address buses 8 to 15 (separate bus mode)

Table 2 2 1	Pin Names and Functions	(1	of $6$	۱
			010	,

Pin name	Number of pins	Input or output	Function
P70-P77	8	Input	Port 7: Port used exclusively for input
AN0-AN7		Input	Analog input: Input from A/D converter
P80-P87	8	Input	Port 8: Port used exclusively for input
AN8-AN15		Input	Analog input: Input from A/D converter
P90-P97	8	Input	Port 9: Port used exclusively for input
AN16-AN23		Input	Analog input: Input from A/D converter
PA0	1	Input/output	Port A0: Input/output port
TB0IN0		Input	16-bit timer 0 input 0: For inputting the count/capture trigger of a 16-bit timer 0
INT5		Input	Interrupt request pin 5: Selectable between "H" level, "L" level, rising edge, and falling edge
		r ···	Input pin with Schmitt trigger
PA1	1	Input/output	Port A1: Input/output port
TB0IN1		Input	16-bit timer 0 input 1: For inputting the count/capture trigger of a 16-bit timer 0
INT6		Input	Interrupt request pin 6: Selectable "H" level, "L" level, rising edge and falling edge
		r	Input pin with Schmitt trigger
PA2	1	Input/output	Port A2: Input/output port
TBOOUT		Output	16-bit timer 0 output: 16-bit timer 0 output pin
PA3	1	Input/output	Port A3: Input/output port
TB1IN0	1	Input	16-bit timer 1 input 0: For inputting the count/capture trigger of a 16-bit timer 1
INT7		Input	Interrupt request pin 7: Selectable between "H" level, "L" level, rising edge and falling edge
1117		mput	Input pin with Schmitt trigger
PA4	1	Input/output	Port A4: Input/output port
TB1IN1	1	Input	16-bit timer 1 input 1: For inputting the count/capture trigger of a 16-bit timer 1
INT8		-	
11110		Input	Interrupt request pin 8: Selectable between "H" level, "L" level, rising edge and falling edge Input pin with Schmitt trigger
PA5	1	Input/output	Port A5: Input/output port
TB1OUT	1		16-bit timer 1 output: 16-bit timer 1 output pin
PA6	1	Output	
	1	Input/output	Port A6: Input/output port
TB2OUT	1	Output	16-bit timer 2 output: 16-bit timer 2 output pin
PA7	1	Input/output	Port A7: Input/output port
TB3OUT		Output	16-bit timer 3 output: 16-bit timer 3 output pin
PB0	1	Input/output	Port B0: Input/output port
TB4OUT		Output	16-bit timer 4 output: 16-bit timer 4 output pin
PB1	1	Input/output	Port B1: Input/output port
TB5OUT		Output	16-bit timer 5 output: 16-bit timer 5 output pin
PB2	1	Input/output	Port B2: Input/output port
TB6OUT		Output	16-bit timer 6 output: 16-bit timer 6 output pin
PB3	1	Input/output	Port B3: Input/output port
TB7OUT		Output	16-bit timer 7 output: 16-bit timer 7 output pin
PB4	1	Input/output	Port B4: Input/output port
TB8OUT		Output	16-bit timer 8 output: 16-bit timer 8 output pin
PB5	1	Input/output	Port B5: Input/output port
TB9OUT		Output	16-bit timer 9 output: 16-bit timer 9 output pin
PB6	1	Input/output	Port B6: Input/output port
TBAIN0		Input	16-bit timer A input 0: for inputting the count/capture trigger of a 16-bit timer A
			2-phase pulse counter input 0
PB7	1	Input/output	Port B7: Input/output port
TBAIN1		Input	16-bit timer A input 1: For inputting the count/capture trigger of a 16-bit timer A
		-	2-phase pulse counter input 1

Table 2.2.1Pin Names and Functions (2 of 6)

Pin name	Number of pins	Input or output	Function
PC0	1	Input/output	Port C0: Input/output port
TXD0		Output	Sending serial data 0: Open drain output pin depending on the program used
PC1	1	Input/output	Port C1: Input/output port
RXD0		Input	Receiving serial data 0
PC2	1	Input/output	Port C2: Input/output port
SCLK0		Input/output	Serial clock input/output 0
CTS0		Input	Ready to send serial data 0 (Clear To Send): Open drain output pin depending on the program used
PC3	1	Input/output	Port C3: Input/output port
TXD1		Output	Sending serial data 1: Open drain output pin depending on the program used
PC4	1	Input/output	Port C4: Input/output port
RXD1		Input	Receiving serial data 1
PC5	1	Input/output	Port C5: Input/output port
SCLK1		Input/output	Serial clock input/output 1
CTS1		Input	Ready to send serial data 1 (Clear To Send): Open drain output pin depending on the program used
PC6	1	Input/output	Port C6: Input/output port
TXD2		Output	Sending serial data 2: Open drain output pin depending on the program used
PC7	1	Input/output	Port C7: Input/output port
RXD2		Input	Receiving serial data 2
PD0	1	Input/output	Port D0: Input/output port
SCLK2		Input/output	Serial clock input/output 2
CTS2		Input	Ready to send serial data 2 (Clear To Send): Open drain output pin depending on the program used
PD1	1	Input/output	Port D1: Input/output port
TXD3		Output	Sending serial data 3: Open drain output pin depending on the program used
PD2	1	Input/output	Port D2: Input/output port
RXD3		Input	Receiving serial data 3
PD3	1	Input/output	Port D3: Input/output port
SCLK3		Input/output	Serial clock input/output 3
CTS3		Input	Ready to send serial data 3 (Clear To Send): Open drain output pin depending on the program used
PD4	1	Input/output	Port D4: Input/output port
TXD4		Output	Sending serial data 4: Open drain output pin depending on the program used
PD5	1	Input/output	Port D5: Input/output port
RXD4		Input	Receiving serial data 4
PD6	1	Input/output	Port D6: Input/output port
SCLK4		Input/output	Serial clock input/output 4
CTS4		Input	Ready to send serial data 4 (Clear To Send): Open drain output pin depending on the program used
PD7	1	Input/output	Port D7: Input/output port
INT9		Input	Interrupt request pin 9: Selectable between "H" level, "L" level, rising edge and falling edge
		_	Input pin with Schmitt trigger

Table 2.2.1 Pin Names and Functions (4 of 6)

Pin name	Number of pins	Input or output	Function
PI3	1	Input/output	Port I3: Input/output port
INT3		Input	Interrupt request pin 3: Selectable between "H" level, "L" level, rising edge and falling edge Input pin with Schmitt trigger
PI4	1	Input/output	Port I4: Input/output port
INT4		Input	Interrupt request pin 4: Selectable between "H" level, "L" level, rising edge and falling edge Input pin with Schmitt trigger
PJ0	1	Input/output	Port J0: Input/output port
DREQ2		Input	DMA request signal 2: For inputting the request to transfer data by DMA from an external I/O device to DMAC2
PJ1	1	Input/output	Port J1: Input/output port
DACK2		Output	DMA acknowledge signal 2: Signal showing that DREQ2 has acknowledged a DMA transfer request
<u>PJ2</u>	1	Input/output	Port J2: Input/output port
DREQ3		Input	DMA request signal 3: For inputting the request to transfer data by DMA from an external I/O device to DMAC3
<u>PJ3</u>	1	Input/output	Port J3: Input/output port
DACK3		Output	DMA acknowledge signal 3: Signal showing that DREQ3 has acknowledged a DMA transfer request
PK0-PK7	8	Input/output	Port K: Input/output port that allows input/output to be set in units of bits
KEY0-KEY7		Input	KEY on wake up input 0 to 7 (with pull-up) With Schmitt trigger
PL0-PL7	8	Input/output	Port L: Input/output port that allows input/output to be set in units of bits
PM0-PM7	8	Input/output	Port M: Input/output port that allows input/output to be set in units of bits
PN0-PN7	8	Input/output	Port N: Input/output port that allows input/output to be set in units of bits
PO0	1	Input/output	Port O0: Input/output port
INT0		Input	Interrupt request pin 0: Selectable between "H" level, "L" level, rising edge and falling edge Input pin with Schmitt trigger
PO1	1	Input/output	Port O1: Input/output port
INT1		Input	Interrupt request pin 1: Selectable between "H" level, "L" level, rising edge and falling edge Input pin with Schmitt trigger
PO2	1	Input/output	Port O2: Input/output port
INT2		Input	Interrupt request pin 2: Selectable between "H" level, "L" level, rising edge and falling edge Input pin with Schmitt trigger
PO3	1	Input/output	Port O3: Input/output port
INT3		Input	Interrupt request pin 3: Selectable between "H" level, "L" level, rising edge and falling edge Input pin with Schmitt trigger
PO4	1	Input/output	Port O4: Input/output port
INT4		Input	Interrupt request pin 4: Selectable between "H" level, "L" level, rising edge and falling edge Input pin with Schmitt trigger
PO5	1	Input/output	Port O5: Input/output port
TXD6		Output	Sending serial data 6: Open drain output pin depending on the program used
PO6	1	Input/output	Port O6: Input/output port
RXD6		Input	Receiving serial data 6
PO7	1	Input/output	Port O7: Input/output port
SCLK6		Input/output	Serial clock input/output 6
CTS6		Input	Ready to send serial data 6 (Clear To Send): Open drain output pin depending on the program used
PP0-PP7	8	Input/output	Port P: Input/output port that allows input/output to be set in units of bits
TPD0-TPD7		Output	Outputting trace data from the data access address: Signal for DSU-ICE
PQ0-PQ7	8	Input/output	Port P: Input/output port that allows input/output to be set in units of bits
TPC0-TPC7		Output	Outputting trace data from the program counter: Signal for DSU-ICE
TPD0-TPD7		Output	Outputting trace data from the data access address: Signal for DSU-ICE

Table 2.2.1 Pin Names and Functions (5 of 6)

Pin name	Number of pins	Input or output	Function
DCLK	1	Output	Debug clock: Signal for DSU-ICE
EJE	1	Input	EJTAG enable: Signal for DSU-ICE (input with Schmitt trigger and built-in noise filter)
PCST4-0	5	Output	PC trace status: Signal for DSU-ICE
DINT	1	Input	Debug interrupt: Signal for DSU-ICE
		-	(input with Schmitt trigger, pull-up and built-in noise filter)
TOVR/TSTA	1	Output	Outputting the status of PD data overflow status: Signal for DSU-ICE
ТСК	1	Input	Test clock input: Signal for testing JTAG (input with Schmitt trigger and pull-up)
TMS	1	Input	Test mode select input: Signal for testing JTAG (input with Schmitt trigger and pull-up)
TDI	1	Input	Test data input: Signal for testing JTAG (input with Schmitt trigger and pull-up)
TDO	1	Output	Test data output: Signal for testing JTAG
TRST	1	Input	Test reset input: Signal for testing JTAG (input with Schmitt trigger and pull-down)
NMI	1	Input	Nonmaskable interrupt request pin: Pin for requesting an interrupt at the falling edge
		-	Input with Schmitt trigger and built-in noise filter
PLLOFF	1	Input	Fix this pin to the "H (DVCC15) level."(Input with Schmitt trigger)
RESET	1	Input	Reset: Initializing LSI (with pull-up)
			Input with Schmitt trigger and built-in noise filter
X1/X2	2	Input/output	Pin for connecting to a high-speed oscillator
XT1/XT2	2	Input/output	Pin for connecting to a low-speed oscillator
BUPMD	1	Input	Backup mode trigger pin: This pin must be set to "L level" in backup mode.
BRESET	1	Input	Backup module reset: Initializing the backup module (with pull-up)
			Input with Schmitt trigger
BUSMD	1	Input	Pin for setting an external bus mode: This pin functions as a multiplexed bus by sampling the
			"H (DVCC15) level" upon the rising of a reset signal. It also functions as a separate bus by
			sampling "L" upon the rising of a reset signal. When performing a reset operation, pull it up or down according to a bus mode to be used.
ENDIAN	1	Input	Pin for setting endian: This pin is used to set a mode. It performs a big-endian operation by
	-		sampling the "H (DVCC15) level" upon the rising of a reset signal, and performs a little-
			endian operation by sampling "L" upon the rising of a reset signal. When performing a reset
		-	operation, pull it up or down according to the type of endian to be used.
BOOT	1	Input	Pin for setting a single boot mode: This pin goes into single boot mode by sampling "L" upon the rising of a reset signal. It is used to overwrite internal flash memory. By sampling "H
			(DVCC15) level" upon the rising of a reset signal, it performs a normal operation. This pin
			should be pulled up under normal operating conditions. Pull it up when resetting.
BW0-1	2	Input	Fix these pins to BW0="H (DVCC15)" and BW1="H (DVCC15)," respectively.
			(Input with Schmitt trigger)
VREFH	1	Input	Pin (H) for supplying the A/D converter with a reference power supply
			Connect this pin to AVCC31 if the A/D converter is not used.
VREFL	1	Input	Pin (L) for supplying the A/D converter with a reference power supply
			Connect this pin to AVSS if the A/D converter is not used.
AVCC31-32	2	_	Pin for supplying the A/D converter with a power supply. Connect it to a power supply even if the A/D converter is not used.
AVSS	3	-	A/D converter GND pin (0 V). Connect this pin to GND even if the A/D converter is not used.
TEST1-3	3	Input	TEST pin: To be fixed to GND.
CVCC15	1	-	Pin for supplying oscillators with power: 1.5 V power supply
CVSS/BVSS	1	_	GND pin (0 V) for oscillators and backup modules
DVCC15	4	_	Power supply pin: 1.5 V power supply
BVCC	1	_	Pin exclusively for supplying backup modules with power: 3 V power supply
DVCC30-34	8	_	Power supply pin: 3 V power supply
DVSS	11	_	GND pin (0 V)

Table 2.2.1 Pin Names and Functions (6 of 6)

Note 1: For BUSMD, ENDIAN and BOOT pins, the state designated for each pin ("H" or "L" level) must be maintained during one system clock before and after the rising of a reset signal. The reset pin must always be in a stable state at both "L" and "H" levels.
Note 2: For DREQ2, DACK2, DREQ3 and DACK3, it is necessary to go to the port function register and to select one port from two groups of ports, PF3 to PF6 and PJ0 to PJ3. Two ports cannot be operated simultaneously to use the same function. Likewise, for pins INT0 through INT4, one port must be selected from ports PI0 to PI4 and ports PO0 to PO4.

Table 2.2.2 shows the pin names and power supply pins.

		(under normal operating conditions)			
		1.8 V to 3.3 V (in BACKUP mode)			

Table 2.2.3 shows the pin numbers and power supply pins.

#### 3. Processor Core

The TMP19A64 has a high-performance 32-bit processor core (TX19A processor core). For information on the operations of this processor core, please refer to the "TX19A Family Architecture."

This chapter describes the functions unique to the TMP19A64 that are not explained in that document.

#### 3.1 Reset Operation

To reset the device, ensure that the power supply voltage is in the operating voltage range, the oscillation of the internal high-frequency oscillator has stabilized at the specified frequency and that the  $\overrightarrow{\text{RESET}}$  input has been "0" for at least 12 system clocks (1.78 µs during external 13.5 MHz operation).

Note that the PLL multiplication clock is quadrupled and the clock gear is initialized to the 1/8 mode during the reset period.

When the reset request is authorized,

- the system control coprocessor (CP0) register of the TX19A processor core is initialized. For further details, please refer to the chapter about architecture.
- After the reset exception handling is executed, the program branches off to the exception handler. The address to which the program branches off to (address where exception handling starts) is called an exception vector address. This exception vector address of a reset exception (for example, nonmaskable interrupt) is 0xBFC0_0000H (virtual address).
- The register of the internal I/O is initialized.
- The port pin (including the pin that can also be used by the internal I/O) is set to a general-purpose input or output port mode.
- (Note 1) Set the RESET pin to "0" before turning the power on. Perform the reset after the power supply voltage has stabilized sufficiently within the operating range.
- (Note 2) The reset operation can alter the internal RAM state, but does not alter data in the backup RAM.
- (Note 3) Make sure that the power supply voltage has stabilized, wait for 500  $\mu s$  or longer, and perform the reset.
- (Note 4) In the FLASH program, the reset period of 0.5 uS or longer is required independently of the system clock.

#### 4. Memory Map

Fig. 4.1 shows the memory map of the TMP19A64.

- (Note 1) The internal ROM is physically present in 0x1FC0_0000-0x1FDF_FFFF (2 MB). The internal RAM is physically present in 0xFFFD_0000-0xFFFD_FFFF (64 KB). 0xFFFF_0000-0xFFFF_DFFF (56 KB) becomes the projection area. You can access the internal RAM by accessing this area. The internal backup RAM area becomes 0xFFFF_E800-0xFFFF_E9FF (512 B).
- (Note 2) For the TMP19A64, a physical space of only 16 MB is available as external address space to be accessed. It is possible to place this 16-MB physical address space in a chip select area of your choice inside the 3.5-GB physical address space of the CPU. Access to internal memory, internal I/O space and reserved areas is given priority over access to the external address space. Therefore, access to the external address space or reserved areas are being accessed.
  (Note 3) Do not place an instruction in the last four words of a physical area, specifically
- (Note 3) Do not place an instruction in the last four words of a physical area, specifically the last four words of an area where memory is mounted for external ROM extension (this varies depending on the system of the user). Internal ROM: 0x1FDF_FFF0-0x1FDF_FFFF

#### 5. Clock/Standby Control

#### 5.1 System Operation Modes

The system operation modes contain the standby modes in which the processor core operations are stopped to reduce power consumption. Fig. 5.1.1 State Transition Diagram of Each Operation Mode is shown below.

State Transition Diagram of Clock Mode When No Power is Supplied to the Backup Module

State Transition Diagram of Clock Mode When Power is Supplied to the Backup Module

- (Note 1) STOP mode: All the circuits except the backup module are brought to a stop. The backup module continues operation (fs continues oscillation).
- (Note 2) External input: It is necessary to activate the BUPMD pin during the RESET period. For details, see the chapter on Backup RAM.

Fig. 5.1.1 State Transition Diagram of Each Operation Mode

#### 5.2 Default State of the System Clock

Fig. 5.2.1 Initial State of the System Clock

fosc:	High-frequency clock frequency to be input via the X1 and X2 pins
fpll:	Clock frequency multiplied (quadrupled) by the PLL
fc:	Clock frequency when the PLLOFF pin is in the "H" state
fs:	Low-frequency clock frequency to be input via the XT1 and XT2 pins
fgear:	Clock frequency selected by the system control register SYSCR1 <gear2:0> in the clock generator</gear2:0>
fsys:	System clock frequency The CPU, ROM, RAM, DMAC and INTC all operate according to this clock. The internal peripheral I/O operates according to the fsys/2 clock.
fperiph	: Clock frequency selected by SYSCR1 <fpsel> (Clock to be input to the peripheral I/O prescaler)</fpsel>

#### 5.3 Clock System Block Diagram

#### 5.3.1 Main System Clock

- Allows for oscillator connection or external clock input.
- Keep the PLLOFF pin (PLL (quadruple)) at the "H" level.
- Clock gear (8/8, 7/8, 6/8, 5/8, 4/8, 2/8, 1/8)

(Default is 1/8.)

• Input frequency (high frequency)

	Input frequency range	Maximum operating frequency	Lowest operating frequency
PLL operation (for both oscillators and external input)	8-13.5 (MHz)	54 MHz	4 MHz *

* Clock gear 1/8 (default) is used when 8 MHz (MIN) is input.

Input frequency (low frequency)

Input frequency range	Maximum operating frequency	Lowest operating frequency
30 KHz to 34 KHz	34 KHz	30 KHz

(Note) (precautions for switching the high-speed clock gear) Switching of clock gear is executed when a value is written to the SYSCR1<GEAR2:0> register. There are cases where switching does not occur immediately after the change in the register setting but the original clock gear is used for execution of instructions. If it is necessary to use the new clock for execution of the instructions following to the clock gear switching instruction, insert a dummy instruction (to execute a write cycle). To use the clock gear, ensure that you make the time setting such that φTn of the prescaler output from each block in the peripheral I/O is calibrated to φTn<fsys/2 (φTn becomes slower than fsys/2). Do not switch the clock gear during operation of the timer counter or other peripheral I/O.
(Note) Restriction on use of the clock gear to operate the peripheral I/O, use the frequency

division ratio of 8/8, 4/8, 2/8 or 1/8. If other frequency division ratios are used, the peripheral I/O will not operate properly.

#### 5.3.2 Clock Gear

- The high-speed clock is divided into 8/8, 7/8, 6/8, 5/8, 4/8, 2/8 or 1/8.
- The internal I/O prescaler clock \$\$\phi\$T0: fperiph/2, fperiph/4, fperiph/8 and fperiph/16

Fig. 5.3.1 shows the system clock transition diagram.

Fig. 5.3.1 System Clock Transition Diagram

#### 5.4.1 System Control Registers

• Don't switch the SYSCK and the GEAR<2:0> simultaneously.

• If the system enters the STOP mode with SYSCR2<DRVOSCH> set at 1 (low capability), the setting will change to 0 (high capability) after the STOP mode is released. Make the setting again, as required.

• SYSCK can be switched when XEN is set to "1."

(Note) Restriction on use of the clock gear

When using the clock gear to operate the peripheral I/O, set the SYSCR1<GEAR2:0> to the frequency division ratio of fc, fc4/8, fc2/8 or fc1/8. If other frequency division ratios are used, the peripheral I/O will not operate properly.

#### 5.5 System Clock Controller

By resetting the system clock controller, the controller status is initialized to  $\langle XEN \rangle =$ "1" and  $\langle GEAR2:0 \rangle =$ "111," and the system clock fsys changes to fc/8. (fc=fosc (original oscillation frequency)×4, because the original oscillation is quadrupled by PLL.) For example, when a 13.5-MHz oscillator is connected to the X1 or X2 pin, fsys becomes 6.25 MHz (=13.5×4×1/8) after the reset.

Similarly, when the oscillator is not connected and an external oscillator is used to input a clock instead, fsys becomes the frequency obtained from the calculation "input frequency $\times 4 \times 1/8$ ."

#### (Note) Set the initial system clock frequency to 4 MHz or higher.

# 5.5.1 Oscillation Stabilization Time (Switching between the NORMAL and SLOW modes)

The warm-up timer is provided to confirm the oscillation stability of the oscillator when it is connected to the oscillator connection pin. The warm-up time can be selected by setting the SYSCR2<WUPT1:0> depending on the characteristics of the oscillator. The SYSCR0<WUEF> is used to confirm the start and completion of warm-up through software (instruction). After the completion of warm-up is confirmed, switch the system clock (SYSCR1<SYSCK>).

When clock switching occurs, the current system clock can be checked by monitoring the SYSCR1<SYSCKFLG>.

Table 5.5.1 shows the warm-up time when switching occurs.

## (Note 1) Warm-up is not required when an oscillator is used for the clock and providing stable oscillation.

(Note 2) The warm-up timer operates according to the oscillation clock, and it can contain errors if there is any fluctuation in the oscillation frequency. Therefore, the warm-up time should be taken as approximate time.

Warm-up time options SYSCR2 <wupt1:0></wupt1:0>	High-speed clock (fosc)
01 ( $2^8$ /oscillation frequency)	18.963 (µs)
10 (2 ¹⁴ /oscillation frequency)	1.214 (ms)
11 (2 ¹⁶ /oscillation frequency)	4.855 (ms)

These values are calculated under the following condition: fosc = 13.5 MHz

<example 1=""></example>	Transition from the NORMAL	mode to the SLOW mode
	SYSCR1 <sysck>="1"</sysck>	: Switch the system clock to low speed (fs)
	SYSCR1 <sysckflg>Read</sysckflg>	: Confirm that the current state is "1" (the current system clock
		<u>is fs)</u>
	SYSCR0 <xen>="0"</xen>	: Disable the high-speed oscillation (fosc)
<example 2=""></example>	Transition from the SLOW mo	de to the NORMAL mode
	SYSCR2 <wupt1:0>="xx"</wupt1:0>	: Select the warm-up time
	SYSCR0 <xen>="1"</xen>	: Enable the high-speed oscillation (fosc)
	SYSCR0 <wuef>="1"</wuef>	: Start the warm-up timer (WUP)
	SYSCR0 <wuef> Read</wuef>	: Wait until the state becomes "0" (WUP is finished)
	SYSCR1 <sysck>="0"</sysck>	: Switch the system clock to high speed (fgear)
	SYSCR1 <sysckflg>Read</sysckflg>	: Confirm that the current state is "0" (the current system clock
		<u>is fgear)</u>

(Note) In the SLOW mode, the CPU operates with the low-speed clock, and the INTC, the backup block, the 2-phase pulse input counter, the KWUP, the IO port and the EBIF (external bus interface) are operable. Stop other internal peripheral functions before the system enters the SLOW mode.

#### 5.5.2 System Clock Pin Output Function

The system clock, fsys, fsys/2 or fs, can be output from the P46/SCOUT pin. By setting the port 4 related registers, P4CR<P46C> to "1" and P4FC<P46F> to "1," the P46/SCOUT pin becomes the SCOUT output pin. The output clock is selected by setting the SYSCR3<SCOSEL1:0>.

Table 5.5.2 shows the pin states in each standby mode when the P46/SCOUT pin is set to the SCOUT output.

Mode			Standby mode		
SCOUT selection	NORMAL	SLOW	IDLE	SLEEP	STOP
<scosel1:0>="00"</scosel1:0>	Output the fs clock.				
<scosel1:0>="01"</scosel1:0>	Output the fpriph clock.		ock.		
<scosel1:0>="10"</scosel1:0>	Output the fsys clock.		ck.	Fixed to	5 01 1.
<scosel1:0>="11"</scosel1:0>	Output the	Fixed to "0."	Output the $\phi$ T0 clock.	Fixed to "0."	

Table 5.5.2 SCOUT Output State in Each Standby Mode

(Note)	The phase difference (AC timing) between the system clock output by the
	SCOUT and the internal clock is not guaranteed.

#### 5.5.3 Reducing the Oscillator Driving Capability

This function is intended for restricting oscillation noise generated from the oscillator and reducing the power consumption of the oscillator when it is connected to the oscillator connection pin.

Setting the SYSCR2<DRVOSCH> to "1" reduces the driving capability of the high-speed oscillator. (low capability)

This is reset to the default setting "0." When the power is turned on, oscillation starts with the normal driving capability (high capability). This is automatically set to the high driving capability state (<DRVOSCH>="0") whenever the oscillator starts oscillation due to mode transition.

• Reducing the driving capability of the high-speed oscillator

Fig. 5.5.1 Oscillator Driving Capability

#### 5.5.4 Clock Frequency Division for Low-Speed System Clock

The low-speed clock (fs) can be divided into two by setting the system control register SYSCR1<SGEAR> to "1." This reduces the power consumption in the SLOW mode. Set the clock frequency division during high-speed oscillation.

#### 5.6 Prescaler Clock Controller

Each internal I/O (TMRB0-A, TMRC, SIO0-6 and SBI) has a prescaler for dividing a clock. The clock  $\phi$ T0 to be input to each prescaler is obtained by selecting the "fperiph" clock at the SYSCR1<FPSEL> and the SYSCR0<PRCK1:0> and then dividing the clock according to the setting of SYSCR0<PRCK1:0>. After the controller is reset, fperiph/16 is selected as  $\phi$ T0. For details, please refer to Fig. 5.3.1 System Clock Transition Diagram.

#### 5.7 Clock Multiplication Circuit (PLL)

Keep the PLLOFF pin at the "H" level. This pin is the circuit that outputs the fpll clock that is a quadruple of the output clock of the high-speed oscillator, fosc. This lowers the oscillator input frequency while increasing the internal clock speed.

#### 5.8 Flash Access Control Circuit (PFB)

The PFBWAIT register can be used to select the speed of access to the flash memory.

You need to set an appropriate flash access speed for the operating frequency to be used.

		31 - 2	1	0
PFBWAIT	bit Symbol	-	PFB	WAIT
(0xFFFF_E500)	Read/Write	R	R/W	R/W
	After reset	0	1	1

PFBWAIT: WAIT number

11: 4-clock access/10: 3-clock access/01: 2-clock access

00: Setting disabled

	Operating frequency (fc) MHz					
PFBWAIT<1:0>	40- < 45 <=54					
11	0	0	0			
10	0	0	0			
01	0	×	×			
00						

O: Settable ×: Not settable -: Setting prohibited

Note) If an appropriate access speed is not specified, the program can operate improperly.

#### 5.9 Standby Controller

The TX19A core has several low-consumption modes. To shift to the STOP, SLEEP or IDLE (Halt or Doze) mode, set the RP bit in the CPO status register, and then execute the WAIT instruction.

Before shifting to the mode, you need to select the standby mode at the system control register (SYSCR2).

The IDLE, SLEEP and STOP modes have the following features:

IDLE: Only the CPU is stopped in this mode.

The internal I/O has one bit of the ON/OFF setting register for operation in the IDLE mode in the register of each module. This enables operation settings for the IDLE mode. When the internal I/O has been set not to operate in the IDLE mode, it stops operation and holds the state when the system enters the IDLE mode.

Table 5.9.1 shows a list of IDLE setting registers.

Internal I/O	IDLE mode setting register
TMRB0-A	TBxRUN <i2tbx></i2tbx>
TBT	TBTRUN <i2tbt></i2tbt>
SIO0-6	SCxMOD1 <i2sx></i2sx>
SBI	SBIBR0 <i2sbi></i2sbi>
A/D converter	ADMOD1 <i2ad></i2ad>
WDT	WDMOD <i2wdt></i2wdt>

Table 5.9.1 Internal I/O Setting Registers for the IDLE Mode

- (Note 1) The Halt mode is activated by setting the RP bit in the status register to "0," executing the WAIT command and shifting to the standby mode. In this mode, the TX19A processor core stops the processer operation while holding the status of the pipeline. The TX19A gives no response to the bus control authority request from the internal DMA, so the bus control authority is maintained in this mode.
- (Note 2) The Doze mode is activated by setting the RP bit in the status register to "1" and shifting to the standby mode. In this mode, the TX19A processor core stops the processer operation while holding the status of the pipeline. The TX19A can respond to the bus control authority request given from the outside of the processor core.
- SLEEP: Only the internal low-speed oscillator, the backup block, the 2-phase pulse input counter operate.
- STOP: All the internal circuits are brought to a stop.

#### 5.9.1 CG Operations in Each Mode

Clock source	Mode	Oscillation circuit	PLL	Clock supply to peripheral I/O	Clock supply to CPU
Oscillator	Normal	0	0	0	0
	Slow	Slow O × P		Partial supply (Note)	0
	Idle (Halt)	t) O O Se		Selectable	х
	Idle (Doze)	0	O Selectable		×
	Sleep	fs only	×	Backup block/2-phase pulse input counter	×
	Stop	×	×	х	х

2-phase counter	0	0			0	×	×
Backup block	0	$\Delta$ (Note 1)			0	O/x	0
						(Note 3)	
KWUP	0	0	0	0	×	0	×
CG	0	0	0	0	0	×	×
High-speed oscillator (fc)	0	$\Delta$ (Note 2)	0	0	×	×	×
Low-speed oscillator (fs)	0	0	0	0	0	0	0

Table 5.9.2 Block Operating Status in Each Operation Mode

O: ON ×: OFF

- Low-speed oscillation is active when the BVCC is applied, and not active when the BVCC is shut off.
- (Note 1) The backup RAM is inaccessible in the SLOW mode.
- (Note 2) When the system enters the SLOW mode, the high-speed oscillator must be stopped by setting the SYSCR1<XEN>.
- (Note 3) In the SLOW mode, the backup block operates differently depending on the BUPMD pin.

#### 5.9.3 Releasing the Standby State

The standby state can be released by an interrupt request when the interrupt level is higher than the interrupt mask level, or by the reset. The standby release source that can be used is determined by a combination of the standby mode and the state of the interrupt mask register <IM15:8> assigned to the status register in the system control coprocessor (CPO) of the TX19A processor core. Details are shown in Table 5.9.3 Standby Release Sources and Standby Release Operations.

• Release by an interrupt request

Operations of releasing the standby state using an interrupt request vary depending on the interrupt enabled state. If the interrupt level specified before the system enters the standby mode is equal to or higher than the value of the interrupt mask register, an interrupt handling operation is executed by the trigger after the standby is released, and the processing is started at the instruction next to the standby shift instruction (WAIT instruction). If the interrupt request level is lower than the value of the interrupt mask register, the processing is started with the instruction next to the standby shift instruction) without executing an interrupt handling operation. (The interrupt request flag is maintained at "1".)

For a nonmaskable interrupt, an interrupt handling is executed after the standby state is released irrespectively of the mask register value.

• Release by the reset

Any standby state can be released by the reset.

Note that releasing of the STOP mode requires sufficient reset time to allow the oscillator operation to become stable. (Refer to Table 5.1.)

When the standby mode is released by the reset, data in the backup RAM can maintain the state immediately before the standby state is started, but other settings will be initialized. (When the standby mode is released by an interruption, the state immediately before the standby state is started will be maintained.)

Please refer to "6. Interrupt" for details of interrupts for STOP, SLEEP and IDLE release and ordinary interrupts.

In	Interrupt accepting state Interrupt enabled EI= "1"		Interrupt accepting state		Interrupt dis	sabled El	= "0"	
	s	tandby mode	IDLE (programmable)	SLEEP	STOP	IDLE (programmable)	SLEEP	STOP
		INTWDT	Ø	×	×	Ø	_	-
е		INT0-B	Ø	Ø	© (Note 1)	0	0	O (Note 1)
e source	at	KWUP0-7	Ø	Ø	© (Note 1)	0	0	O (Note 1)
release	Interrupt	INTRTC	Ø	O	×	0	0	×
	Inte	INTTBA (Note 2)	Ø	O		0	0	
Standby		INTTB0-9	Ø	×	×	0	×	×
Sta		INTRX0-6, TX0-6	Ø	×	×	0	×	×
		INTS	Ø	×	×	0	×	×
		INTAD/ADHP/ADM	Ø	×	×	0	×	×

#### Table 5.9.3 Standby Release Sources and Standby Release Operations (Interrupt level)>(Interrupt mask)

© : Starts the interrupt handling after the standby mode is released. (The LSI is initialized by the reset.)

O: Starts the processing at the address next to the standby instruction (without executing the interrupt handling) after the standby mode is released.

 $\times$  : Cannot be used for releasing the standby mode

- : Cannot execute masking with an interruption mask when a nonmaskable interrupt is selected.

(Note 1) The standby mode is released after the warm-up time has elapsed.

- (Note 2) These operations are applicable only when the 2-phase pulse input counter mode is selected. If any other modes are selected, the operations will be the same as those for the INTTB0 to INTTB9.
  - To release the standby mode by using the level mode interrupt in the interruptible state, keep the level until the interrupt handling is started. Changing the level before then will prevent the interrupt processing from starting properly.
  - To enter the standby mode when the CPU has disabled the acceptance of interrupts, disable interrupts other than the recovery factors in advance by using the interrupt controller (INTC). Otherwise, the standby mode can be released by any other interrupts than the recovery factors.
  - To recover from the standby mode when the CPU has disabled the acceptance of interrupts, set the interrupt level higher than the interrupt mask (Interrupt level > Interrupt mask). If the interrupt level is equal to or lower than the interrupt mask (Interrupt level ≤ Interrupt mask), the system cannot recover from the standby mode.

#### 5.9.4 STOP Mode

In the STOP mode, all the internal circuits, including the internal oscillators, are brought to a stop. The pin states in the STOP mode vary depending on the setting of the SYSCR2<DRVE>. Table 5.9.6 shows the pin states in the STOP mode. When the STOP mode is released, the system clock output is started after the elapse of warm-up time at the warm-up counter to allow the internal oscillators to stabilize. After the STOP mode is released, the system returns to the operation mode that was active immediately before the STOP mode (NORMAL or SLOW), and starts the operation.

It is necessary to make these settings before the instruction to enter the STOP mode is executed. Specify the warm-up time at the SYSCR2<WUPT1:0>.

# (Note) To shift from the NORMAL mode to the STOP mode on the TMP19A64, do not set the SYSCR2<WUPT1:0> to "00" or "01" for the warm-up time setting. The internal system recovery time cannot be satisfied when the system recovers from the STOP mode.

Transition of operation mode	Warm-up setting
NORMAL $\rightarrow$ IDLE	Not required
NORMAL $\rightarrow$ SLEEP	Not required
NORMAL $\rightarrow$ SLOW	Not required
NORMAL $\rightarrow$ STOP	Not required
$IDLE \rightarrow NORMAL$	Not required
SLEEP $\rightarrow$ NORMAL	Required
$SLEEP \rightarrow SLOW$	Not required
$SLOW \rightarrow NORMAL$	Required (Note 1)
$SLOW \rightarrow SLEEP$	Not required
$SLOW \rightarrow STOP$	Not required
$STOP \rightarrow NORMAL$	Required
$\text{STOP} \rightarrow \text{SLOW}$	Not required

Table 5.9.4 Warm-up Settings for Transitions of Operation Modes

Note 1) When the high-speed oscillator is stopped in the SLOW mode

#### (NOTE) 19A64 requires a recovery time from Warming up state as following

State Transition Diagram						
WUP Trigger	State	Running Mode after WUP	Minimum required Operation time			
	Transition		before WAIT instruction done (sec)			
STOP release	Α	STOP/SLEEP	64 / (fsys) in NOMAL mode			
STOP refease	В	STOP/SLEEP	16 / (fsys) in SLOW mode			
SLEEP release	С	STOP/SLEEP	64 / (fsys) in NOMAL mode			
SEELI TETEASE	D	STOP/SLEEP	_			

#### 5.9.5 Recovery from the STOP or SLEEP Mode

1. Transition of operation modes: NORMAL  $\rightarrow$  STOP  $\rightarrow$  NORMAL

2. Transition of operation modes: NORMAL  $\rightarrow$  SLEEP  $\rightarrow$  NORMAL

Table 5.9.6 Pin States in the STOP Mode in Each State of SYSCR2<DRVE> (2/2)

Output : The pin is in the output state.

PU^{*} : This is the programmable pull-up pin. The input gate is always disabled. No feedthrough current flows even if the high impedance is selected.

[:] Indicates that the input is disabled for the input mode and the input pin and the impedance becomes high for the output mode and the output pin. Note that the input is enabled when the port function register (PxFC) is "1" and the port control register (PxCR) is "0."

Input : The input gate is active. To prevent the input pin from floating, fix the input voltage to the "L" or "H" level.

### 6. Interrupts

### 6.1 Overview

The features of the TX19A64 interrupts are as follows:

- 2 interrupts from the CPU itself (software interrupt instruction)
- 21 external pins ( NMI , INTO to INTB, KWUP0 to 7)
- 51 interrupts from internal I/O (including WDT interrupt)
- Generation of vectors for each interrupt factor
- Seven interrupt levels for each interrupt factor
- An interrupt can be used to activate the DMAC.
- (1) Preparation for interrupt settings
  - Settings required before generating interrupts:
    - Set the exception table base address (the base address of the table of maskable interrupt jump addresses) to IVR.

Set the interrupt jump addresses to the "exception table base address + IVR offset address" memory. Set Status  $\langle IM [4:2] \rangle$  of the CP0 register to "0x111."

* For details of the Status register, refer to the material "TX19A Core Architecture."

Fig. 6.1.1 Interrupt Connection Diagram

(2)	Inte	rrupt	s from external pins (INTO - INTB and I	KV	VUP0-7)
	Wh	en an	y external interrupt is to be used for sett	ing	g to clear the Standby mode, use the following steps:
		1	Set ports		
		2	Set functions		
		3	Set CG		
		4	Clear the EICRCG and INTCLR regist	ers	s of CG
		5	Enable interrupts with INT		
	a)	INT	°0 - INTB		
		• I	f it is used to clear the Stop mode:		
			IMCGx <emcgx2:0> = "xxx"</emcgx2:0>	:	Set the standby clear request of each interrupt (INT0-B) to "active" (Refer to INTCG register).
			IMCGx <intxen> = "1"</intxen>	:	Set the clear input of each interrupt (INT0-B) to "enable" (Refer to INTCG register).
			EICRCG <icrcg3:0>= "xxxx"</icrcg3:0>	:	Clear each interrupt request (INT0-B) (Refer to INTCG register).
			INTCLR <eiclr8:0> = "000000100"</eiclr8:0>	:	Clear interrupt requests INT0-B (Refer to INTCG register).
			IMCx <eimx1:0> = "01"</eimx1:0>	:	Set each interrupt request (INT0-B) to the H level (Refer to INTC register).
	b)	KW	/UP0-7		
		• I	f it is used to clear the Stop mode:		
			IMCGD <emcgc1:0>= "01"</emcgc1:0>	:	Set the KWUP standby clear request to "active" (Refer to INTCG register).
			IMCGD <kwupen> = "1"</kwupen>	:	Set the KWUP clear input to "enable" (Refer to INTCG register).
			IMC3 <eimd1:0> = "01"</eimd1:0>	:	Set KWUP interrupt request to the H level (Refer to INTC register).
			IMC3 <eimd1:0> = "01"</eimd1:0>	:	Clear KWUP interrupt request (Refer to INTCG register).
			INTCLR <eiclr8:0> = "000110100"</eiclr8:0>	:	Clear KWUP interrupt request (Refer to INTCG register).
			KWUPST <keyint7:0> = "1"</keyint7:0>	:	Set each KWUP interrupt factor to Enable (Refer to KWUP register).

### Table 6.1.2 Registers to be Set for Detecting Interrupts

	Interrupt	Interrupt detection levels that can be used
INTO - INTB,I	(WUP	When in use, set to a rising edge in INTC (if edge detection is set for CG) or to "H" level (if level detection is set for CG). Set the active state in CG. The "L" level, "H" level, falling edge, or rising edge setting can be selected in CG register.
Internal I/O	Others	Falling edge

(Note 1) Interrupt level 0 means that the interrupt is disabled.

- (3) Interrupt operation
  - Basic interrupt handling

O In the interrupt handler (Refer to Table 6.2.1 Interrupt Jump Address for the starting address of the interrupt handler):

- Read the IVR value (in the figure, IVR value is 0x8000)
- Substitute the IVR value for ICLR to clear the interrupt factor.
- Obtain the exception handling jump address by using the IVR value (in the figure, it is 0x8000) as the corresponding address in the table (in the figure, the "jump to" address is 0x9000).
- Jump to the exception handling routine using the "jump to" address.

O In the interrupt processing routine:

- Execute the interrupt processing
- Set ILEV <MLEV> = 0 to return to the mask level before the exception is generated.
- Command "ERET" to return to the routine before the exception is generated.

Note that interrupts are disabled during the exception handling except for the case multiple interrupts are allowed.

Fig. 6.1.3 Process Flow in the Interrupt Handler

### 6.2 Interrupt Factor

The starting address of an exception handler is defined as "exception vector address." The exception vector address for a reset exception and non-maskable interrupts is  $0xBFC0_0000$ . The exception vector address for a debug exception is  $0xBFC0_0480$  (EJTAG ProbEn = 0). For other exceptions, the corresponding exception vector addresses are determined depending on the BEV bit of Status register [23] and the IV bit of the Cause register [23] of the system control coprocessor register (CP0).

	BE	V=0	BEV=1			
Exception	Virtual address	Virtual address Logical address		Logical address		
Reset	0xBFC0_0000	0x1FC0_0000	0xBFC0_0000	0x1FC0_0000		
EJTAG Debug (En=0)	0xBFC0_0480	0x1FC0_0480	0xBFC0_0480	0x1FC0_0480		
EJTAG Debug (En=1)	0xFF20_0200	0xFF20_0200	0xFF20_0200	0xFF20_0200		
Interrupt (IV=0)	0x8000_0180	0x0000_0180	0xBFC0_0380	0x1FC0_0380		
Interrupt (IV=1)	0x8000_0200	0x0000_0200	0xBFC0_0400	0x1FC0_0400		
All others	0x8000_0180	0x0000_0180	0xBFC0_0380	0x1FC0_0380		

Table 6.2.1 Interrupt Branch Address

- (Note 1) If vector addresses are to be placed in the internal ROM, set the status bit <BEV> of the system control coprocessor register (CP0) to "1."
- (Note 2) The "software interrupt," which is a maskable interrupt, can be generated by setting IP [1:0] of the Cause register of CP0. This "software interrupt" is different from the "software set," which is one of the hardware interrupt factors. The "software set" interrupt is generated by setting <IL02:0> of the IMC0 register in the interrupt controller (INTC) to any value other than "0."

Interrupt Number	IVR[8:0]		Interrupt Factor	Interrupt Control Register	Address

### Table 6.2.2 List of Hardware Interrupt Factors

Number	Interrupt Factor	Note
0	INT0	External interrupt 0
1	INT1	External interrupt 1
2	INT2	External interrupt 2
3	INT3	External interrupt 3
4	INT4	External interrupt 4
5	INT5	External interrupt 5
6	INT6	External interrupt 6
7	INT7	External interrupt 7
8	INT8	External interrupt 8
9	INT9	External interrupt 9
10	INTA	External interrupt A
11	INTB	External interrupt B
12	KWUP	Key on wake up interrupt
13	INTRTC	Clock timer interrupt
14	INTTBA	Two-phase pulse input counter interrupt
15	reserved	

Table 6.2.3 Interrupt Factors to Cancel Stop/Sleep/Idle Modes

* Number 0 to 13 interrupt factors can cancel Stop/Sleep modes.

* Number 14 interrupt factor can cancel the Sleep mode.

* Each factor can clear the IDLE mode.

### 6.3 Interrupt Detection

If any interrupt is used to cancel the Stop mode, interrupt active states of INT0 to INTB must be set in the EMCGxx field of the IMCGx register in CG and the EIMxx of the IMCx register in INTC must be set to "H" level. For KWUP0 to 7, the EMCG field of the IMCGD register in CG must be set to "H" and the EIMxx field of the IMCx register in INTC must be set to "H" level. The active state as well as enable/disable is set in KWUPSTn for each interrupt. For setting other interrupts, the EIMxx field of the IMCx register in INTC is used. Four types of active states, "H" level, "L" level, rising edge, and falling edge, are used. When the interrupt detection circuit of TMP19A64 recognizes that any input state matches with the predefined active state, it notifies the processor core or INTC of an interrupt request. If the interrupts that can be used to cancel the Stop mode are not to be used for canceling Stop mode, it is unnecessary to configure them in CG. In this case, INT0 to INTB can be set only by INTC and KWUP0 to 7 can be set in INTC and KWUPSTx.

The interrupt signal is negated by the interrupt handler after the interrupt factor is identified.

In the case of INT0 to INTB, appropriate values are written to the ICRCG field of the EICRCG register and to the EICLR field of the INTCLR register in INTC. KWUP0 to 7 are negated by setting KWUPCLR. Other interrupt signals are negated by writing a given value in the EICLR field of the INTCLR register in the INTC. To negate the interrupt factor whose active state is level-sensitive, an external circuit that has asserted the INTx signal must be operated so that it negates INTx. However, please ensure that the level input is not negated until the specified interrupt vector (IVR) has been read.

## (Note) Please ensure that each setting is performed in the order of setting the active state, clearing an interrupt request, and enabling an interrupt.

IMCGA <emcg01:00></emcg01:00>	= "10"	:	Set INTO active state to falling edge.
EICRCG <icrcg3:0></icrcg3:0>	= "0000"	:	Clear the INTO interrupt request.
IMCGA <int0en></int0en>	= "1"	:	Enable INT0 cancel input.
IMC0 <eim11:10></eim11:10>	= "01"	:	Set INT0 to "H" level.
INTCLR <eiclr8:0></eiclr8:0>	= "000000100"	:	Clear the INTO interrupt request.
IMC0 <il12:10></il12:10>	= "101"	:	Set the interrupt level of "5."
Status <ie> = "1," <im></im></ie>	= "xxx"		TX19A processor core

(Example INT0 setting to cancel Stop mode)

### 6.4 Interrupt Priority Arbitration

(1) Seven levels of interrupt priority

Seven levels of priority are available and each interrupt factor can be assigned to one of these levels. The interrupt level is set by the interrupt mode control register (IMCx) which has a 3-bit field (ILx) for level settings. The greater the value (interrupt level) set in IMCx <ILx2:0>, the higher the priority. If the value is set to "000" meaning the interrupt level of 0, no interrupts will be generated by the factor.

(2) Interrupt level notification

If an interrupt is generated, the INTC notifies the TX19A processor core of the interrupt level. The TX19A processor core identifies the interrupt level by reading the values in the IP field in the Cause register. If two or more interrupts (with different interrupt levels) are generated simultaneously, the INTC notifies the TX19A processor core of the highest-level interrupt factor and the lower level interrupt factors are suspended.

(3) Interrupt vector (notification of interrupt factor)

If an interrupt is generated, the INTC sets the corresponding interrupt factor vector in the vector register (IVR). The TX19A processor core identifies the interrupt factor by reading the vector register value. If two or more interrupts (with the same interrupt level) are generated simultaneously, the INTC notifies the TX19A processor core of the factor of which request number is younger. When no interrupt factors have been generated, the IVR <8:2> field is "0" (By clearing interrupt requests, the IVR register is cleared to "0.")

### 6.5 INTC Register

Address Register symbol		Register	Corresponding interrupt number
0xFFFF_E000	IMC0	Interrupt mode control register 0	3 - 0
0xFFFF_E004	IMC1	Interrupt mode control register 1	7 - 4
0xFFFF_E008	IMC2	Interrupt mode control register 2	11 - 8
0xFFFF_E00C	IMC3	Interrupt mode control register 3	15 - 12
0xFFFF_E010	IMC4	Interrupt mode control register 4	19 - 16
0xFFFF_E014	IMC5	Interrupt mode control register 5	23 - 20
0xFFFF_E018	IMC6	Interrupt mode control register 6	27 - 24
0xFFFF_E01C	IMC7	Interrupt mode control register 7	31 - 28
0xFFFF_E020	IMC8	Interrupt mode control register 8	35 - 32
0xFFFF_E024	IMC9	Interrupt mode control register 9	39 - 36
0xFFFF_E028	IMCA	Interrupt mode control register A	43 - 40
0xFFFF_E02C	IMCB	Interrupt mode control register B	47 - 44
0xFFFF_E030	IMCC	Interrupt mode control register C	51 - 48
0xFFFF_E034	IMCD	Interrupt mode control register D	55 - 52
0xFFFF_E038	IMCE	Interrupt mode control register E	59 - 56
0xFFFF_E03C	IMCF	Interrupt mode control register F	63 - 60
0xFFFF_E040	IVR	Interrupt vector register	
0xFFFF_E060	INTCLR	Interrupt request clear register	
0xFFFF_E10C	ILEV	Interrupt level register	

### Table 6.5.1 INTC Register Map

(Note) Unless otherwise specified, the above registers must be 32-bit accessed for both reading and writing.

### 6.5.1 Interrupt Vector Register (IVR)

The vector of each interrupt factor to be generated is listed below.

		7	6	5	4	3	2	1	0			
IVR	bit Symbol	IVR7	IVR6	IVR5	IVR4	IVR3	IVR2	IVR1	IVR0			
(0xFFFF_E040)	Read/Write	IVICI	R

	Function											

#### 6.5.2 **Interrupt Level Register**

		7	6	5	4	3	2	1	0				
ILEV	bit Symbol	_		PMASK0		—	CMASK						
(0xFFFF_E10C)	Read/Write			R		<u>.</u>		R/W (Note 1)					
	After reset	0		000		0		000					
	Function	Always reads "0."	Interrupt ma	ask level (pre	vious) 0	Always reads "0."	Interrupt ma	ask level (cur	rent)				
		15	14	13	12	11	10	9	8				
	bit Symbol	—		PMASK2		—		PMASK1					
	Read/Write		R										
	After reset	0		000		0		000					
	Function	Always reads "0."	Interrupt ma	ask level (pre	vious) 2	Always reads "0."	Interrupt ma	ask level (pre	vious) 1				
		23	22	21	20	19	18	17	16				
	bit Symbol	—		PMASK4		—	PMASK3						
	Read/Write		•			R	-						
	After reset	0		000		0	000						
	Function	Always reads "0."	Interrupt ma	ask level (pre	vious) 4	Always reads "0."	Interrupt ma	ask level (pre	vious) 3				
		31	30	29	28	27	26	25	24				
	bit Symbol	MLEV		PMASK6		—	PMASK5						
	Read/Write	W				R							
	After reset	0		000		0		000					
	Function	Interrupt level change 0: Decrement the interrupt level by 1 1: Change CMASK	Interrupt ma	ask level (pre	vious) 6	Always reads "0."	Interrupt ma	ask level (pre	vious) 5				

- Note 1) Upon setting MLEV to "1," set the CMASK value simultaneously. The PMASKx values are unchanged.
- When <MLEV> is set to "0," the interrupt mask levels in the register shift back to the previous state Note) such that PMASK0 is moved to CMASK and PMASK1 is moved to PMASK0, and so on. The last <PMASK6> is set to "000." If it is to be used after the interrupt process, set MLEV to "0" before executing the ERET command.

This register must be 32-bit accessed. Note)

When a new interrupt is generated, the corresponding interrupt level is stored in CMASK and any Note) previously stored values are shifted in their mask levels such that the previous CMASK is saved in PMASK0 and PMASK0 is saved in PMASK1 and so on.

### 6.5.3 Transition of Interrupt Mask Level

The transition sequence of the interrupt level register is illustrated below.

Fig. 6.5.3 Transition of Interrupt Mask Level

#### Interrupt Level Register (IMCx) 6.5.4

The interrupt level, active state, and whether it is a factor to activate DMAC or not are set for each interrupt factor.

### Note 1: Please ensure that the type of active state is selected before enabling an interrupt request.

Note 2: When making interrupt requests DMAC activation factors, please ensure that you put the DMAC into standby mode after setting the INTC.

#### 6.5.5 Interrupt Request Clear Register

Read/Write

After reset

Function

This register is used to clear interrupt requests. Interrupt requests are cleared by setting the IVR <IVR8:0> value.

		7	6	5	4	3	2	1			
INTCLR	bit Symbol	EICLR7	EICLR6	EICLR5	EICLR4	EICLR3	EICLR2	EICLR1			
(0xFFFF_E060)	Read/Write		R/W								
	After reset	0	0	0	0	0	0	0			
	Function	Set the IV	R <ivr8:0> v</ivr8:0>	value that co	rresponds to	the interrupt	request that	you would l			
		15	14	13	12	11	10	9			
	bit Symbol										
	Read/Write	R									
	After reset	0									
	Function			Al	ways reads "	'0."					
		23	22	21	20	19	18	17			
	bit Symbol	/				/					
	Read/Write	R									
	After reset					0					
	Function				Always r	eads "0."					
		31	30	29	28	27	26	25			
	bit Symbol	/	/	/	/	/					

(Note 1) Do not clear interrupt requests before reading the IVR value. If an interrupt request is cleared, IVR is cleared to "0."

R

0

Always reads "0."

- (Note 2) To make the interrupt controller (INTC) disable specified interrupt requests, perform the following steps in the order shown:
  - ① Disable the processor core to accept interrupts (Status  $\langle IE \rangle = 0$ ).
  - ② Disable the INTC to accept interrupts (IMCxx<ILx2:0> = 000).
  - **③** Execute the SYNC instruction.
  - ④ Enable the processor core to accept interrupts (Status <IE> = 1).

Example)		r0, r0,	r31 IMC**	; _DI ( ); ; IMC**=0;
	sync mtc0	\$sp,	r31	;        _SYNC( ); ;        _EI ( );

(Note 3) Any internal DMA request initiated by an interrupt factor will not be cleared. When the request is to be canceled, clear the activation factor bit of (IMCx) <DMxx>.

#### INTCG Registers (Interrupts to clear Stop, Sleep and Idle modes) 6.5.6

- INTO to INTB, KWUP0 to KWUP7: STOP/SLEEP/IDLE
- INTRTC, INTTBA (Two-phase pulse input counter): Sleep

### 7. Input/Output Ports

### 7.1 Port 0 (P00 through P07)

The port 0 is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register POCR. A reset allows all bits of POCR to be cleared to "0" and the port 0 to be put in input mode.

Besides the general-purpose input/output function, the port 0 performs other functions: D0 through D7 function as a data bus and AD0 through AD7 function as an address data bus. When external memory is accessed, the port 0 automatically functions as either a data bus or an address data bus, and all bits of POCR are cleared to "0." If the BUSMD pin is set to "L" level during a reset, the port 0 is put in separate bus mode (D0 to D7). If it is set to "H" level during a reset, the port 0 is put in multiplexed mode (AD0 to AD7).

Fig. 7.1.2 Port 0 Registers

### 7.2 Port 1 (P10 through P17)

The port 1 is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register P1CR and the function register P1FC. A reset allows all bits of the output latch P1, P1CR and P1FC to be cleared to "0" and the port 1 to be put in input mode.

Besides the general-purpose input/output function, the port 1 performs other functions: D8 through D15 function as a data bus, AD8 through AD15 function as an address data bus, and A8 through A15 function as an address bus. To access external memory, the port 1 must be designated as an address bus or address data bus by making proper P1CR and P1FC settings.

If the BUSMD pin is set to "L" level during a reset, the port 1 is put in separate bus mode (D8 to D15). If it is set to "H" level during a reset, the port 1 is put in multiplexed mode (AD8 to AD15 or A8 to A15).

(BUSMD="1")			ess bus through A	(8) output se	tting			1		1	TORT

Fig. 7.2.2 Port 1 Registers

### 7.3 Port 2 (P20 through P27)

The port 2 is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register P2CR and the function register P2FC. A reset allows all bits of the output latch P2 to be set to "1," all bits of P2CR and P2FC to be cleared to "0," and the port 2 to be put in input mode.

Besides the general-purpose input/output port function, the port 2 performs another function: A0 through A7 function as one address bus and A16 through A23 function as the other address bus. To access external memory, registers P2CR and P2FC must be provisioned to allow the port 2 to function as an address bus.

If the BUSMD pin is set to "L" level during a reset, the port 2 is put in separate mode (A16 to A23). If it is set to "H" level during a reset, the port 2 is put in multiplexed mode (A0 through A7 or A16 through A23).

(*1) The same address bus (A7 through A0/A23 through A16) output settings are used in both the separate bus mode and the multiplexed bus mode (BUSMD="0," "1").

Fig. 7.3.2 Port 2 Registers

#### 7.4 Port 3 (P30 through P37)

The port 3 is a general-purpose, 8-bit input/output port (P30 and P31 are used exclusively for output). For this port, inputs and outputs can be specified in units of bits by using the control register P3CR and the function register P3FC.

A reset allows the output latches P30 and 31 to be set to "1." If the BUSMD pin is at the "L" level when a reset is performed, P37 goes into separate bus mode, and the output latch is set to "1." If the BUSMD pin is at the "H" level when a reset is performed, P37 goes into multiplexed bus mode, and the output latch is cleared to "0." Bit 2 through bit 6 of P3CR (bits 0 and 1 are unused) are cleared to "0." Bit 7 of P3CR is cleared to "0" in separate bus mode. All bits of P3FC are cleared to "0," P30 and P31 generate "H," and P32 through P36 go into the input mode with a pull-up resistor after RESET is cleared. If the port 3 goes into separate bus mode, P37 is put into input mode. If the port 3 goes into multiplexed bus mode, P37 is put into output mode.

Besides the general-purpose input/output port function, the port 3 inputs and outputs CPU control/status signals. If the P30 pin is set to  $\overline{\text{RD}}$  signal output mode (<P30F>="1"), the  $\overline{\text{RD}}$  strobe is output only when an external address area is accessed. Likewise, if the P31 pin is set to  $\overline{\text{WR}}$  signal output mode (<P31F>="1"), the  $\overline{\text{WR}}$  strobe is output only when an external address area is accessed.

As for P32 and P36, when <P3xFC> ="1," and BUSAK ="0," Pull-up is enabled.

(*1) In separate bus mode (BUSMD="0"), ALE is not output. The port 3 functions as an input/output port based on the bit setting of the control register P3CR<P37C>. After a reset, the port becomes an input port. If a reset is executed in multiplexed bus mode (BUSMD="1"), the port 3 becomes an output port at "L" level.

(*2) /RD and /WR are output only when an external area is being accessed.

Fig. 7.4.6 Port 3 Registers

#### 7.5 Port 4 (P40 through P47)

The port 4 is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register P4CR and the function register P4FC. A reset allows all bits of the output latch P4 to be set to "1" and all bits of P4CR to be reset to "0." Bits of P40FC through P46FC are reset to "0." P40 through P45 goes into the input mode with a pull-up resistor, and P46 and P47 are put into input mode.

Besides the general-purpose input/output port function, the ports 40 through 45 outputs chip select signals (CS0 through  $\overline{\text{CS5}}$ ), and the port 46 functions as a SCOUT output pin for outputting external clocks.

#### 7.6 Port 5 (P50 through P57)

The port 5 is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register P5CR and the function register P5FC. A reset allows all bits of the output latch P5 to be set to "1," all bits of P5CR and P5FC to be cleared to "0," and the port 5 to be put in input mode.

The port 5 also functions as an address bus (A0 through A7). To access external memory, P5CR and P5FC must be provisioned to allow the port 5 to function as an address bus. This address bus function can be used only in separate bus mode. (To put the port 5 in separate bus mode, the BUSMD pin must be set to "L" level during a reset.)

Fig. 7.6.2 Port 5 Registers

#### 7.7 Port 6 (P60 through P67)

The port 6 is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register P6CR and the function register P6FC. A reset allows all bits of the output latch P6 to be set to "1," all bits of P6CR and P6FC to be cleared to "0," and the port 6 to be put in input mode. Besides the input/output port function, the port 6 performs other functions: P60 and P63 output SIO data, P61 and P64 input SIO data, P62 and P65 input and output SIO CLK or input CTS, P61 and P64 input external interrupts, and P66 and P67 output a 16-bit timer.

The port 6 also functions as an address bus (A8 through A15). To access external memory, P6CR and P6FC must be provisioned to allow the port 6 to function as an address bus. The address bus function can be used only in separate bus mode. (To put the port 6 in separate bus mode, the BUSMD pin must be set to "L" level during a reset.)

#### 7.9 Port A (PA0 through PA7)

The port A is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register PACR. A reset allows PACR to be reset to "0" and the port A to function as an input port. Besides the input/output port function, the port A performs other functions: PA2, PA5, PA6 and PA7 output a 16-bit timer, and PA0, PA1, PA3 and PA4 input a 16-bit timer and external interrupts. These functions are enabled by setting corresponding bits of PAFC to "1." A reset allows PACR and PAFC to be cleared to "0" and the port A to be put in input mode.

Port A register

SYSCR<DRVE> is set to 0. In all other cases, this bit setting does not need to be used.

#### If two input functions in addition to the PORT function are assigned to one pin, which input (Note) function to be used shall be designated by making proper enable/disable settings provided in each function block.

Fig. 7.9.3 Port A Registers

#### 7.10 Port B (PB0 through PB7)

Port B is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register PBCR. A reset allows PBCR to be reset to "0" and the port B to function as an input port. Besides the input/output port function, the port B performs other functions: PB0 through PB5 output a 16-bit timer, and PB6 and PB7 input a 16-bit timer. These functions are enabled by setting corresponding bits of PBFC to "1." A rest allows PBCR and PBFC to be cleared to "0" and the port B to function as an input port.

#### 7.11 Port C (PC0 to PC7)

Port C is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register PCCR. A reset allows PCCR to be reset to "0" and the port C to function as an input port. Besides the input/output port function, the port C performs other functions: PC0, PC3 and PC6 output SIO data, PC1, PC4 and PC7 input SIO data, and PC2 and PC5 input and output SIO CLK or input CTS. These functions are enabled by setting corresponding bits of PCFC to "1." A reset allows PCCR and PCFC to be cleared to "0" and the port C to function as an input port.

# 7.12 Port D (PD0 to PD7)

The port D is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register PDCR. A reset allows PDCR to be reset to "0" and the port D to function as an input port. Besides the input/output port function, the port D performs other functions: PD0, PD3 and PD6 input and output SIO CLK or input CTS, PD1 and PD4 output SIO data, PD2 and PD5 input SIO data, and PD7 inputs external interrupts. These functions are enabled by setting corresponding bits of PDFC to "1." A reset allows PDCR and PDFC to be cleared to "0" and the port D to function as an input port.

# 7.13 Port E (PE0 through PE7)

The port E is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register PECR. A reset allows PECR to be reset to "0" and the port E to function as an input port. Besides the input/output port function, the port E performs other functions: PE0 outputs SIO data, PE1 inputs SIO data, PE2 inputs and outputs SIO CLK or inputs CTS, and PE6 and PE7 input external interrupts. These functions are enabled by setting corresponding bits of PEFC to "1." A reset allows PECR and PEFC to be cleared to "0" and the port E to function as an input port.

Port E register

(*1) This bit setting is used only if an interrupt must be generated to clear the STOP status and if SYSCR<DRVE> is set to 0. In all other cases, this bit setting does not need to be used.

Fig. 7.13.6 Port E Registers

# 7.14 Port F (PF0 through PF7)

The port F is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register PFCR. A reset allows PFCR to be reset to "0" and the port F to function as an input port. Besides the input/output port function, the port F performs other functions: PF0 through PF2 input and output SB1, PE3 and PE5 input the DMA request signal, PF4 and PF6 output the DMA acknowledge signal, and PF7 inputs external clock sources of a 32-bit time base timer. These functions are enabled by setting corresponding bits of PFFC to "1." A reset allows PFCR and PFFC to be cleared to "0" and the port F to function as an input port. The DMAC function is shared by PF3 through PF6 and PJ0 through PJ3. To give PF0 through PF3 the precedence in using the DMAC function, the corresponding bit of PFFC must be set to "1."

# 7.17 Port I (PI0 through PI4)

The port I is a general-purpose, 5-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register PICR. A reset allows PICR to be reset to "0" and the port I to function as an input port. Besides the input/output port function, the port I performs another function: PIO through PI4 input external interrupts. This function is enabled by setting the corresponding bit of PIFC to "1." A reset allows PICR and PIFC to be cleared to "0" and the port I to function as an input port. The external interrupt function is shared by PIO through PI4 and PO0 through PO4. To give PO0 through PO4 the precedence in using the external interrupt function, the corresponding bit of POFC must be set to the interrupt function.

(Note*1) This SYSC	bit setting is CR <drve> i</drve>		-	-		-						

(Note) The external interrupt function is shared by the port I and the port O. If both ports are set to use the external interrupt function, the port O is given priority in using the external interrupt function.

Fig. 7.17.2 Port I Registers

# 7.18 Port J (PJ0 through PJ3)

The port J is a general-purpose, 4-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register PJCR. A reset allows PJCR to be reset to "0" and the port J to function as an input port. Besides the input/output port function, the port J performs other functions: PJ0 and PJ2 input the DMA request signal, and PJ1 and PJ3 output the DMA acknowledge signal. These functions are enabled by setting the corresponding bits of PJFC to "1." A reset allows PJCR and PJFC to be cleared to "0" and the port J to function as an input port. The DMAC function is shared by PJ0 through PJ3 and PF3 through PF6. To give PF0 through PF3 the precedence in using the DMAC function over PJ0 through PJ3, the corresponding bit of PFFC must be set to "1."

Fig. 7.18.3 Port J Registers

# 7.19 Port K (PK0 through PK7)

The port K is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register PKCR. A reset allows PKCR to be reset to "0" and the port K to function as an input port. Besides the input/output port function, PK0 through PK7 perform the KEY input function. This function is enabled by setting the corresponding bit of PKFC to "1." A reset allows PKCR and PKFC to be cleared to "0" and the port K to function as an input port.

The ports K0 through K7 have a pull-up resistor function. This function is enabled only if KUPPUP<KEYPUPn> of the key-on wake-up circuit is set to "1" and if KEY input is enabled by KWUPSTn. For further details, refer to the section where key-on wake-up is discussed. If these ports are in operation, the pull-up function is disabled.

# 7.23 Port O (PO0 through PO7)

The port O is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register POCR. Besides the input/output port function, the port O performs another function: PO0 through PO4 input external interrupts. This function is enabled by setting the corresponding bit of POFC to "1." A rest allows POCR and POFC to be cleared to "0" and the port O to function as an input port. The external interrupt function is shared by PO0 through PO4 and PI0 through PI4. To give PO0 through PO4 the precedence in using the external interrupt function, the corresponding bit of POFC must be set to the interrupt function.

SYSCR<DRVE> is set to 0. In all other cases, this bit setting does not need to be used.

(Note) The external interrupt function is shared by the port 1 and the port 0. If both ports are set to use the external interrupt function, the port 0 is given priority in using the external interrupt function.

Fig. 7.23.5 Port O Registers

# 7.24 Port P (PP0 through PP7)

The port P is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register PPCR. Besides the input/output port function, the port P performs another function: PP0 through PP7 output the signal for EJTAG. This function is enabled by a combination of the EJTAG debug level and the corresponding bit of PPFC. A reset allows PPCR and PPFC to be cleared to "0" and the port P to function as an input port.

If DSU-ICE is used for debugging, the port P outputs the signal for EJTAG. Therefore, it is recommended not to use the port P as an input/output port.

(Note) The above system diagram does not show the debug function.

Note) For information on debug levels and other details, refer to the DSU Probe Handling Manual.

# 7.25 Port Q (PQ0 through PQ7)

The port Q is a general-purpose, 8-bit input/output port. For this port, inputs and outputs can be specified in units of bits by using the control register PQCR. Besides the input/output port function, PQ0 through PQ7 output the signal for EJTAG. This function is enabled by a combination of a debug level and the corresponding bit of PPFC. A reset allows PQCR and PPFC to be cleared to "0" and the port Q to function as an input port. If DSU-ICE is used for debugging, the port Q outputs the signal for EJTAG. Therefore, it is recommended not to use the port Q as an input/output port.

Fig. 7.25.1 Port Q (PQ0 through PQ7)

(Note) The above system diagram does not show the debug function.

# 8. External Bus Interface

The TMP19A64 has a built-in external bus interface function to connect to external memory, I/Os, etc. This interface consists of an external bus interface circuit (EBIF), a chip selector (CS) and a wait controller.

The chip selector and wait controller designate mapping addresses in a 6-block address space and also control wait states and data bus widths (8- or 16-bit) in these and other external address spaces.

The external bus interface circuit (EBIF) controls the timing of external buses based on the chip selector and wait controller settings. The EBIF also controls the dynamic bus sizing and the bus arbitration with the external bus master.

- External bus mode Selectable address, data separator bus mode and multiplex mode
- Wait function

This function can be enabled for each block.

- A wait of up to 7 clocks can be automatically inserted.
- A wait can be inserted via the WAIT/RDY pin.
- Data bus width

Either an 8- or 16-bit width can be set for each block.

- Recovery cycle (read/write)
   If an external bus cycle is in progress, a dummy cycle of up to 2 clocks can be inserted and this dummy cycle can be specified for each block.
- Recovery cycle (chip selector)
   When an external bus is selected, a dummy cycle of up to 1 clock can be inserted and this dummy cycle can be specified for each block.
- Bus arbitration function

### 8.1 Address and Data Pins

#### (1) Address and data pin settings

The TMP19A64 can be set to either separate bus or multiplexed bus mode. Setting the BUSMD pin to the "L" level at a reset activates the separate bus mode, and setting the pin to the "H" level activates the multiplexed bus mode. Port pins 0, 1, 2, 5 and 6, which are to be connected to external devices (memory), are used as address buses, data buses and address/data buses. Table 8.1.1 shows these.

	Separate BUSMD="L"	Multiplex BUSMD="H"
Port 0 (P00 to P07)	D0-D7	AD0-AD7
Port 1 (P10 to P17)	D8-D15	AD8-AD15/A8-A15
Port 2 (P20 to P27)	A16-A23	A0-A7/A16-A23
Port 5 (P50 to P57)	A0-A7	General-purpose port
Port 6 (P60 to P67)	A8-A15	General-purpose port
Port 37 (P37)	General-purpose port	ALE

Table 8.1.1 Bus Mode, Address and Data Pins

Each port is put into input mode after a reset. To access an external device, set the address and data bus functions by using the port control register (PnCR) and the port function register (PnFC).

In the multiplex mode, the four types of functions can be selected, as shown in Table 8.1.2, by setting the port registers (PnCR and PnFC).

		0	0	3	4	
Number of address buses		max.24 (-16 MB)	max.24 (-16 MB)	max.16 (-64 KB)	max.8 (-256 B)

Table 8.1.2 Address and Data Pins in the Multiplex Mode

(Note 1) Even in cases of ③ and ④, address outputs are available as the data bus pins are also used for address buses.

(Note 2) Ports 0 to 2 are put into input modes after a reset, and they do not serve as address or data bus pins.

(Note 3) Any of ^① to ^④ can be selected by setting the P1CR, P1FC, P2CR and P2FC registers.

(2) Address HOLD when an internal area is accessed

When an internal area is being accessed, the address bus maintains the address output of the previously accessed external area and doesn't change it. Also, the data bus is in a state of high impedance.

### 8.2 Data Format

### 8.3 External Bus Operations (Separate Bus Mode)

This section describes various bus timing values. The timing diagram shown below assumes that the address buses are A23 through A0 and that the data buses are D15 through D0.

(1) Basic bus operation

The external bus cycle of the TMP19A64 basically consists of three clock pulses and a wait can be inserted as mentioned later. The basic clock of an external bus cycle is the same as the internal system clock.

Fig. 8.3.1 shows read bus timing and Fig. 8.3.2 shows write bus timing. If internal areas are accessed, address buses remain unchanged as shown in these figures. Additionally, data buses are in a state of high impedance and control signals such as  $\overline{RD}$  and  $\overline{WR}$  do not become active.

Fig. 8.3.1 Read Operation Timing Diagram

Fig. 8.3.2 Write Operation Timing Diagram

#### (2) Wait timing

A wait cycle can be inserted for each block by using the chip selector (CS) and wait controller. The following three types of wait can be inserted:

- ① A wait of up to 7 clocks can be automatically inserted.
- ② A wait can be inserted via the WAIT pin (2+2N, 3+2N, 4+2N, 5+2N, 6+2N, 7+2N). Note: 2N is the number of external waits that can be inserted.
- ③ A wait can be inserted via the RDY pin (2+2N, 3+2N, 4+2N, 5+2N, 6+2N, 7+2N). Note: 2N is the number of external waits that can be inserted.

The setting of the number of waits to be automatically inserted and the setting of the external wait input can be made using the chip selector and wait controller registers, BmnCS<BnW>.

Fig. 8.3.3 through Fig. 8.3.10 show the timing diagrams in which waits have been inserted.

Fig. 8.3.3 Read Operation Timing Diagram (0 Wait and 1 Wait Automatically Inserted)

Fig. 8.3.4 Read Operation Timing Diagram (5 Waits Automatically Inserted)

TOSHIBA

Fig. 8.3.5 shows the read operation timing when 0 wait, waits automatically inserted, and waits automatically inserted + external waits are inserted in the separate bus mode.

Fig. 8.3.5 Read Operation Timing Diagram

Fig. 8.3.6 shows the write operation timing when 0 wait, waits automatically inserted, and waits automatically inserted + external waits are inserted in the separate bus mode.

Fig. 8.3.6 Write Operation Timing Diagram

By setting the bit 3 < P33F > of port 3 function register P3FC to "1," the WAIT input pin (P33) can also serve as the  $\overline{RDY}$  input pin.

The RDY input is input to the external bus interface circuit as the logical reverse of the WAIT input. The number of waits is specified by the chip selector and wait controller register, BmnCS<BnW>.

Fig. 8.3.7 shows the RDY inputs and the number of waits.

Fig. 8.3.7 RDY Input and Wait Operation Timing Diagram

(3) Time that it takes before ALE is asserted

When the external bus of the TMP19A64 is used as a multiplexed bus, the ALE width (assert time) can be specified by using the system control register SYSCR3 <ALESEL> in the CG. In the case of a separate bus mode, ALE is not output, but the time from when an address is established to the assertion of the  $\overline{RD}$  or  $\overline{WR}$  signal is different depending on the SYSCR3<ALESEL>.

During a reset,  $\langle ALESEL \rangle = "1"$  is set and the  $\overline{RD}$  or WR signal is asserted as a point of two system (internal) clocks after an address is established. If  $\langle ALESEL \rangle$  is cleared to "0," the  $\overline{RD}$  or  $\overline{WR}$  signal is asserted at a point of one system (internal) clock after an address is established. This assert setting cannot be established for each block in an external area and the same setting is commonly used in an external address space.

Fig. 8.3.13 SYSCR3<ALESEL> Set Value and External Bus Operation

(4) Recovery time

If access to external areas occurs consecutively, a dummy cycle can be inserted for recovery time.

A dummy cycle can be inserted in both a read and a write cycle. The dummy cycle insertion setting can be made in the chip selector and wait controller registers, BmnCS<BnWCV> (write recovery cycle) and <BnRCV> (read recovery cycle). As for the number of dummy cycles, one or two system clocks (internal) can be specified for each block. Fig. 8.3.14 shows the timing of recovery time insertion.

Fig. 8.3.14 Timing of Recovery Time Insertion

(5) Chip selector recovery time

If access to external areas occurs consecutively, a dummy cycle can be inserted for recovery time.

The dummy cycle insertion setting can be made in the chip selector and wait controller registers, BmnCS<BnCSCV>. As for the number of dummy cycles, one system clock (internal) can be specified for each block. Fig. 8.3.15 shows the timing of recovery time insertion.

### 8.4 External Bus Operations (Multiplexed Bus Mode)

This section describes various bus timing values. The timing diagram shown below assumes that the address buses are A23 through A16 and that the address/data buses are AD15 through AD0.

(1) Basic bus operation

The external bus cycle of the TMP19A64 basically consists of three clock pulses and a wait can be inserted as mentioned later. The basic clock of an external bus cycle is the same as the internal system clock.

Fig. 8.4.1 shows read bus timing and Fig. 8.4.2 shows write bus timing. If internal areas are accessed, address buses remain unchanged and the ALE does not output latch pulse as shown in these figures. Additionally, address/data buses are in a state of high impedance and control signals such as  $\overline{RD}$  and  $\overline{WR}$  do not become active.

Fig. 8.4.1 Read Operation Timing Diagram

Fig. 8.4.2 Write Operation Timing Diagram

#### (2) Wait Timing

A wait cycle can be inserted for each block by using the chip selector (CS) and wait controller. The following three types of wait can be inserted:

- 0 A wait of up to 7 clocks can be automatically inserted.
- ② A wait can be inserted via the WAIT pin (2+2N, 3+2N, 4+2N, 5+2N, 6+2N, 7+2N). Note: 2N is the number of external waits that can be inserted.
- A wait can be inserted via the RDY pin (2+2N, 3+2N, 4+2N, 5+2N, 6+2N, 7+2N).
   Note: 2N is the number of external waits that can be inserted.

The setting of the number of waits to be automatically inserted and the setting of the external wait input can be made using the chip selector and wait controller registers, BmnCS<BnW>.

Fig. 8.4.3 shows the read operation timing when 0 wait, waits automatically inserted, and waits automatically inserted + external waits are inserted in the multiplexed bus mode.

Fig. 8.4.3 Read Operation Timing Diagram

Fig. 8.4.4 shows the write operation timing when 0 wait, waits automatically inserted, and waits automatically inserted + external waits are inserted in the multiplexed bus mode.

Fig. 8.4.4 Write Operation Timing Diagram

(3) Time that it takes before ALE is asserted

Either 1 clock or 2 clocks can be selected as the time that it takes before ALE is asserted. The setting bit is located in the system clock control register. The default is 2 clocks. This assert setting cannot be established for each block in an external area and the same setting is commonly used in an external address space.

Fig. 8.4.12 Time That It Takes Before ALE Is Asserted

Fig. 8.4.13 shows the timing when the ALE is 1 clock or 2 clocks.

Fig. 8.4.13 Read Operation Timing Diagram (When the ALE is 1 Clock or 2 Clocks)

(4) Read and Write Recovery Time

If access to external areas occurs consecutively, a dummy cycle can be inserted for recovery time.

A dummy cycle can be inserted in both a read and a write cycle. The dummy cycle insertion setting can be made in the chip selector and wait controller registers, BmnCS<BnWCV> (write recovery cycle) and <BnRCV> (read recovery cycle). As for the number of dummy cycles, one or two system clocks (internal) can be specified for each block. Fig. 8.4.14 shows the timing of recovery time insertion.

When read/write recovery is inserted (ALE width:1fsys)

Fig. 8.4.14 Timing of Recovery Time Insertion

(5) Chip selector recovery time

If access to external areas occurs consecutively, a dummy cycle can be inserted for recovery time.

The dummy cycle insertion setting can be made in the chip selector and wait controller registers, BmnCS<BnCSCV>. As for the number of dummy cycles, one system clock (internal) can be specified for each block. Fig. 8.4.15 shows the timing of recovery time insertion.

When chip selector recovery is inserted (ALE width:1fsys)

### 8.5 Bus Arbitration

The TMP19A64 can be connected to an external bus master. The arbitration of bus control authority with the external bus master is executed by using the two signals,  $\overline{\text{BUSRQ}}$  and  $\overline{\text{BUSAK}}$ . The external bus master can acquire control authority for TMP19A64 external buses only, and cannot acquire control authority for internal buses.

(1) Accessible range of external bus master

The external bus master can acquire control authority for TMP19A64 external buses only, and cannot acquire control authority for internal buses (G-BUS). Therefore, the external bus master cannot access the internal memories or the internal I/O. The arbitration of bus control authority for external buses is executed by the external bus interface circuit (EBIF), and this is independent of the CPU and the internal DMAC. Even when the external bus master holds the external bus control authority, the CPU and the internal DMAC can access the internal ROM, RAM and registers. On the other hand, if the CPU or the internal DMAC tries to access an external memory when the external bus master holds the external bus control authority, the CPU or the internal DMAC has to wait until the external bus master releases the bus. For this reason, if the BUSRQ remains active, the TMP19A64 can lock.

(2) Acquisition of bus control authority

The external bus master requests the TMP19A64 for bus control authority by asserting the BUSRQ signal. The TMP19A64 samples the  $\overline{\text{BUSRQ}}$  signal at the break of external bus cycles on the internal buses (G-BUS) and determines whether or not to give the bus control authority to the external bus master. When it gives the bus control authority to the external bus master, it asserts the  $\overline{\text{BUSAK}}$  signal. At the same time, it makes address buses, data buses and bus control signals ( $\overline{\text{RD}}$  and  $\overline{\text{WR}}$ ) in a state of high impedance. (The internal pull-up is enabled for the R/W, HWR and  $\overline{\text{CSx}}$ .)

Depending on the relationship between the size of data to be loaded or stored and the external memory bus width, two or more bus cycles can occur in response to a single data transfer (bus sizing). In this case, the end of the last bus cycle is the break of external bus cycles.

If access to external areas occurs consecutively on the TMP19A64, a dummy cycle can be inserted. Again, requests for buses are accepted at the break of external bus cycles on the internal buses (G-BUS). During a dummy cycle, the next external bus cycle is already started on the internal buses. Therefore, even if the  $\overline{BUSRQ}$  signal is asserted during a dummy cycle, the bus is not released until the next external bus cycle is completed.

Keep asserting the BUSRQ signal until the bus control authority is released.

Fig. 8.5.1 shows the timing of acquiring bus control authority by the external bus master.

- ① BUSRQ is at the "H" level.
- ② The TMP19A64 recognizes that the BUSRQ is at the "L" level, and releases the bus at the end of the bus cycle.
- ③ When the bus is completed, the TMP19A64 asserts BUSAK. The external bus master recognizes that the  $\overline{\text{BUSAK}}$  is at the "L" level, and acquires the bus control authority to start bus operations.

Fig. 8.5.1 Bus Control Authority Acquisition Timing

(3) Release of bus control authority

The external bus master releases the bus control authority when it becomes unnecessary. If the external bus master no longer needs the bus control authority that it has held, it deasserts the  $\overline{\text{BUSRQ}}$  signal and returns the bus control authority to the TMP19A64.

Fig. 8.5.2 shows the timing of releasing unnecessary bus control authority.

- ① The external bus master has the bus control authority.
- ^② The external bus master deasserts the BUSRQ, as it no longer requires the bus control authority.
- ③ The TMP19A64 recognizes that the BUSRQ is at the "H" level, and deasserts the BUSAK.

Fig. 8.5.2 Timing of Releasing Bus Control Authority

# 9. The Chip Selector and Wait Controller

The TMP19A64 can be connected to external devices (I/O devices, ROM and SRAM).

6-block address spaces (CS0 through CS5) can be established in the TMP19A64 and three parameters can be specified for each 4-block address and other address spaces: data bus width, the number of waits and the number of dummy cycles.

CS0 through CS5 (also used as P40 through P45) are the output pins corresponding to spaces CS0 through CS5. These pins generate chip selector signals (for ROM and SRAM) to each space when the CPU designates an address in which spaces CS0 through CS5 are selected. For chip selector signals to be generated, however, the port 4 controller register (P4CR) and the port 4 function register (P4FC) must be set appropriately.

The specification of the spaces CS0 through CS5 is to be performed with a combination of base addresses (BAn, n=0 to 5) and mask addresses (MAn, n=0 to 5) using the base and mask address setting registers (BMA0 through BMA5).

Meanwhile, master enable, data bus width, the number of waits and the number of dummy cycles for each address space are specified in the chip selector and wait controller registers (B01CS, B23CS, B45CS and BEXCS).

A bus wait request pin ( $\overline{WAIT}$ ) is provided as an input pin to control the status of these settings.

### 9.1 Specifying Address Spaces

Spaces CS0 through CS5 are specified using the base and mask address setting registers (BMA0 through BMA5).

In each bus cycle, a comparison is made to see if each address on the bus is located in the space CS0 through CS5. If the result of a comparison is a match, it is considered that the designated CS space has been accessed and chip selector signals are output from pins  $\overline{CS0}$  through  $\overline{CS5}$  and the operations specified by the chip selector and wait controller registers (B01CS, B23CS and B45CS) are executed. (Refer to "9.2 The Chip Selector and Wait Controller.")

#### 9.1.1 Base and Mask Address Setting Registers

Figures 9.1.1 to 3 show base and mask address setting registers. For base addresses (BA0 through BA5), a start address in the space CS0 through CS5 is specified. In each bus cycle, the chip selector and wait controller compare values in their registers with addresses and those addresses with address bits masked by the mask address (MA0 through MA5) are not compared. The size of an address space is determined by the mask address setting.

#### (1) Base addresses

Base address BAn specifies the higher-order 16 bits (A31 through A16) of the start address. The lower-order 16 bits (A15 to A0) of the start address are always set to "0." Therefore, the start address begins with 0x0000_0000H and increases in 64 kilobyte units.

Fig. 9.1.4 shows the relationship between the start address and the BAn value.

#### (2) Mask addresses

Mask address (MAn) specifies which address bit value is to be compared. The address on the bus that corresponds to the bit for which "0" is written on the address mask MAn is to be included in address comparison to determine if the address is in the area of the CS0 to CS5 spaces. The bit for which "1" is written is not included in address comparison.

CS0 to CS5 spaces have different address bits that can be masked by MA0 to MA5.

CS0 space and CS1 space: A29 through A14

CS2 space and CS3 space: A30 through A15  $\,$ 

CS4 space and CS5 space: A30 through A15  $\,$ 

(Note) Address settings must be made using physical addresses.

# The size of both the CS4 and CS5 spaces can be a minimum of 32 KB to a maximum of 2 GB. The external address space of the TMP19A64 is 16 MB and so bits 9 through 15 must be set to "0" as addresses A24 through A30 are not masked.

Fig. 9.1.3 Base and Mask Address Setting Registers (BMA4, BMA5)

Fig. 9.1.4 Start and Base Address Register Values

#### 9.1.2 How to Define Start Addresses and Address Spaces

• To specify a space of 64 KB starting at 0xC000_0000 in the CS0 space, the base and mask address registers must be programmed as shown below.

Values to be set in the base and mask address registers (BMA0)

In the base address (BA0), specify "0xC000" that corresponds to higher 16 bits of a start address, while in the mask address (MA0), specify whether a comparison of addresses in the space A29 through A16 is to be made or not. To ensure a comparison of A29 through A16, set bits 15 to 2 of the mask address (MA0) to "0." A comparison of addresses of A31 and A30 will definitely be made.

This setting allows A31 through A16 to be compared with the value specified as a start address. As A15 through A0 are masked, a space of 64 KB from  $0xC000_0000$  to  $0xC000_FFFF$  is designated as a CS0 space and the CSO signal is asserted if there is a match with an address on the bus.

• To specify a space of 1 MB starting at 0x1FD0_0000 in the CS2 space, the base and mask address registers must be programmed as shown below.

Values to be set in the base and mask address registers (BMA2)

In the base address (BA2), specify "0x1FD0" that corresponds to higher 16 bits of a start address, while in the mask address (MA2), specify whether a comparison of addresses in the space A30 through A15 is to be made or not. To ensure a comparison of A30 through A20, set bits 15 to 5 of the mask address (MA2) to "0." A comparison of A31 will definitely be made.

This setting allows A31 through A20 to be compared with the value specified as a start address. As A19 through A0 are masked, a space of 1 MB from 0x1FD0_0000 to 0x1FDF_FFFF is designated as a CS2 space.

# Note: The CSn signal is not asserted to the following address spaces in the TMP19A64: 0x1FC0_0000 to 0x1FCF_FFFF 0x4000_0000 to 0x400F_FFFF 0xFFFD_6000 to 0xFFFD_FFFF, 0xFFFF_6000 to 0xFFFF_DFFF

After a reset, the CS0, CS1, and CS3 through CS5 spaces are disabled, while the whole CS2 space (4 GB) is enabled as an address space.

Table 9.1.1 shows the relationship between CS space and space sizes. If two or more address spaces are specified simultaneously, a space or spaces with a smaller space number will be given priority in space selection.

Example: 0xC000_0000 as a start address of the CS0 space with a space size of 16 KB 0xC000_0000 as a start address of the CS1 space with a space size of 64 KB

Table 9.1.1 CS Space and Space Sizes
--------------------------------------

Size (bytes) CS space	16 K	32 K	64 K	128 K	256 K	512 K	1 M	2 M	4 M	8 M	16 M
CS0	0	0	0	0	0	0	0	0	0	0	0
CS1	0	0	0	0	0	0	0	0	0	0	0
CS2		0	0	0	0	0	0	0	0	0	0
CS3		0	0	0	0	0	0	0	0	0	0
CS4		0	0	0	0	0	0	0	0	0	0
CS5		0	0	0	0	0	0	0	0	0	0

# 9.2 The Chip Selector and Wait Controller

Fig. 9.2.1 to Fig. 9.2.4 show the chip selector and wait controller registers. For each address space (spaces CS0 through CS5 and other address spaces), each chip selector and wait controller register (B01CS through B45CS, BEXCS) can be programmed to set master enable or disable, to select data bus width, to specify the number of waits and to insert dummy cycles.

If two or more address spaces are specified simultaneously, a space or spaces with a smaller space number will be given priority in space selection (order of priority: CS0>CS1>CS2>CS3>CS4>CS5>EXCS).

Fig. 9.2.4 Chip Selector and Wait Controller Registers

A reset of the TMP19A64 allows the port 4 controller register (P4CR) and the port 4 function register (P4FC) to be cleared to "0," and the CS signal output is disabled. To output the CS signals, set the corresponding bits to "1" at the P4FC and the P4CR in that order. The CS recovery time can be configured in any other areas than the CS setting areas, but CS signals will not be output.

# **10. DMA Controller (DMAC)**

The TMP19A64 has a built-in 8-channel DMA Controller (DMAC).

#### 10.1 Features

The DMAC of the TMP19A64 has the following features:

- (1) DMA with 8 independent channels
- (2) Two types of requests for bus control authority: With and without snoop requests
- (3) Transfer requests: Internal requests (software initiated)/external requests (external interrupts, interrupt requests given by internal peripheral I/Os, and requests given by the DREQ pin) Requests given by the DREQ pin (CH2, 3): Level mode (memory → memory)

Edge mode (memory  $\rightarrow$  I/O, I/O to memory)

- (4) Transfer mode: Dual address mode
- (5) Transfer devices: Memory-to-memory, memory-to-I/O, I/O-to-memory
- (6) Device size: 32-bit memory (8 or 16 bits can be specified using the CS/WAIT controller); I/O of 8, 16 or 32 bits
- (7) Address changes: Increase, decrease, fixed, irregular increase, irregular decrease
- (8) Channel priority: Fixed (in ascending order of channel numbers)
- (9) Endian switchover function

### 10.2 Configuration

#### 10.2.1 Internal Connections of the TMP19A64

Fig. 10.2.1 shows the internal connections with the DMAC in the TMP19A64.

(Note) In Fig. 10.1, signals indicated by * are internal signals.

Fig. 10.2.1 DMAC Connections in the TMP19A64

The DMAC has eight DMA channels. Each of these channels handles the data transfer request signal ( $\overline{INTDREQn}$ ) from the interrupt controller and the acknowledgment signal ( $\overline{DACKn}$ ) generated in response to INTDREQn, where "n" is a channel number from 0 to 7. External pins ( $\overline{DREQ2}$  and  $\overline{DREQ3}$ ) are internally wired to allow them to function as pins of the port F and J. To use them as pins of the port F and J, they must be selected by setting the function control register PFFC and PJFC to an appropriate setting. If both ports are set to use the DMAC function, the port F is given priority in using the DMAC function.

Pins,  $\overline{DACK2}$  and  $\overline{DACK3}$ , handle the data transfer request and acknowledge signal output supplied through external pins,  $\overline{DREQ2}$  and  $\overline{DREQ3}$ . Channel 0 is given higher priority than channel 1, channel 1 higher priority than channel 2 and channel 2 higher priority than channel 3. Subsequent channels are given priority in the same manner.

The TX19A processor core has a snoop function. Using the snoop function, the TX19A processor core opens the core's data bus to the DMAC, thus allowing the DMAC to access the internal ROM and RAM linked to the core. The DMAC is capable of determining whether or not to use this snoop function. For further information on the snoop function, refer to 10.2.3 "Snoop Function."

Two types of bus control authority (SREQ and GREQ) are available to the DMAC and which type of control right to use depends on the use or nonuse of the snoop function. GREQ is a request for bus control authority if the DMAC does not use the snoop function, while SREQ is a request for bus control authority if the DMAC uses the snoop function. SREQ is given higher priority than GREQ.

#### 10.2.2 DMAC Internal Blocks

Fig. 10.2.2 shows the internal blocks of the DMAC.

Fig. 10.2.2 DMAC Internal Blocks

#### 10.2.3 Snoop Function

The TX19A processor core has a snoop function. If the snoop function is activated, the TX19A processor core opens the core's data bus to the DMAC and suspends its own operation until the DMAC withdraws a request for bus control authority. If the snoop function is enabled, the DMAC can access the internal RAM and ROM and therefore designate the RAM or ROM as a source or destination.

If the snoop function is not used, the DMAC cannot access the internal RAM or ROM. However, the G-Bus is opened to the DMAC. If the TX19A processor core attempts to access memory or the I/O by way of the G-Bus and if the DMAC does not accept a bus control release request, bus operations cannot be executed and, as a result, the pipeline stalls.

(Note) If the snoop function is not used, the TX19A processor core does not open the data bus to the DMAC. If the data bus is closed and the internal RAM or ROM is designated as a DMAC source or destination, an acknowledgment signal will not be returned in response to a DMAC transfer bus cycle and, as a result, the bus will lock.

# 10.3 Registers

The DMAC has fifty-one 32-bit registers. Table 10.3.1 shows the register map of the DMAC.

Address	Register symbol	Register name
0xFFFF_E200	CCR0	Channel control register (ch. 0)
0xFFFF_E204	CSR0	Channel status register (ch. 0)
0xFFFF_E208	SAR0	Source address register (ch. 0)
0xFFFF_E20C	DAR0	Destination address register (ch. 0)

Bit	Mnemonic	Field name	Description
31	Rstall	Reset all	Performs a software reset of the DMAC. If the Rstall bit is set to 1, the values of all the internal registers of the DMAC are reset to their initial values. All transfer requests are canceled and all eight channels go into an idle state. 0: Don't care 1: Initializes the DMAC
7	Rst7	Reset 7	<ul> <li>Performs a software reset of the DMAC channel 7. If the Rst7 bit is set to 1, internal registers of the DMAC channel 7 and a corresponding bit of the channel 7 of the RSR register are reset to their initial values. The transfer request of the channel 7 is canceled and the channel 7 goes into an idle state.</li> <li>0: Don't care</li> <li>1: Initializes the DMAC channel 7</li> </ul>
6	Rst6	Reset 6	<ul> <li>Performs a software reset of the DMAC channel 6. If the Rst6 bit is set to 1, internal registers of the DMAC channel 6 and a corresponding bit of the channel 6 of the RSR register are reset to their initial values. The transfer request of the channel 6 is canceled and the channel 6 goes into an idle state.</li> <li>0: Don't care</li> <li>1: Initializes the DMAC channel 6</li> </ul>
5	Rst5	Reset 5	<ul> <li>Performs a software reset of the DMAC channel 5. If the Rst5 bit is set to 1, internal registers of the DMAC channel 5 and a corresponding bit of the channel 5 of the RSR register are reset to their initial values. The transfer request of the channel 5 is canceled and the channel 5 goes into an idle state.</li> <li>0: Don't care</li> <li>1: Initializes the DMAC channel 5</li> </ul>

#### Fig. 10.3.1 DMA Control Register (DCR) (1 of 2)

Bit	Mnemonic	Field name	Description
4	Rst4	Reset 4	<ul> <li>Performs a software reset of the DMAC channel 4. If the Rst4</li> <li>bit is set to 1, internal registers of the DMAC channel 4 and a corresponding bit of the channel 4 of the RSR register are reset to their initial values. The transfer request of the channel 4 is canceled and the channel 4 goes into an idle state.</li> <li>0: Don't care</li> <li>1: Initializes the DMAC channel 4</li> </ul>
3	Rst3	Reset 3	Performs a software reset of the DMAC channel 3. If the Rst3 bit is set to 1, internal registers of the DMAC channel 3 and a corresponding bit of the channel 3 of the RSR register are reset to their initial values. The transfer request of the channel 3 is canceled and the channel 3 goes into an idle state. 0: Don't care 1: Initializes the DMAC channel 3
2	Rst2	Reset 2	Performs a software reset of the DMAC channel 2. If the Rst2 bit is set to 1, internal registers of the DMAC channel 2 and a corresponding bit of the channel 2 of the RSR register are reset to their initial values. The transfer request of the channel 2 is canceled and the channel 2 goes into an idle state. 0: Don't care 1: Initializes the DMAC channel 2
1	Rst1	Reset 1	<ul> <li>Performs a software reset of the DMAC channel 1. If the Rst1 bit is set to 1, internal registers of the DMAC channel 1 and a corresponding bit of the channel 1 of the RSR register are reset to their initial values. The transfer request of the channel 1 is canceled and the channel 1 goes into an idle state.</li> <li>0: Don't care</li> <li>1: Initializes the DMAC channel 1</li> </ul>
0	Rst0	Reset 0	Performs a software reset of the DMAC channel 0. If the Rst0 bit is set to 1, internal registers of the DMAC channel 0 and a corresponding bit of the channel 0 of the RSR register are reset to their initial values. The transfer request of the channel 0 is canceled and the channel 0 goes into an idle state. 0: Don't care 1: Initializes the DMAC channel 0

Fig. 10.3.1 DMA Control Register (DCR) (2 of 2)

(Note 1) If a write to the DCR register occurs during a software reset right after the last round of DMA transfer is completed, the interrupt to stop DMA transfer is not canceled although the channel register is initialized.

(Note 2) An attempt to execute a write (software reset) to the DCR register by DMA transfer must be strictly avoided.

# 10.3.2 Channel Control Registers (CCRn) (n=0 through 7)

Bit	Mnemonic	Field name	Description			
31	Str	Channel start	Start (initial value: 0)			
			Starts channel operation. If this bit is set to 1, the channel goes into a standby mode and starts to transfer data in response to a transfer request.			
			Only a write of 1 is valid to the Str bit and a write of 0 is ignored. A read always returns a 0.			
			1: Starts channel operation			
24		(Reserved)	This is a reserved bit. Always set this bit to "0."			
23	NIEn Normal completion interrupt enable		Normal Completion Interrupt Enable (initial value: 1)			
			1: Normal completion interrupt enable			
			0: Normal completion interrupt disable			
22	AbIEn	Abnormal completion	Abnormal Completion Interrupt Enable (initial value: 1)			
		interrupt enable	1: Abnormal completion interrupt enable			
			0: Abnormal completion interrupt disable			
21		(Reserved)	This is a reserved bit. Although its initial value is "1," always set this bit to "0."			
20		(Reserved)	This is a reserved bit. Always set this bit to "0."			
19		(Reserved)	This is a reserved bit. Always set this bit to "0."			
18		(Reserved)	This is a reserved bit. Always set this bit to "0."			

Fig. 10.3.2 Channel Control Register (CCRn) (1 of 3)

Bit	Mnemonic	Field name	Description
17	Big	Big-endian	Big Endian (initial value: 1)
	Ū.	Ū.	1: A channel operates by big-endian
			0: A channel operates by little-endian
16		(Reserved)	This is a reserved bit. Always set this bit to "0."
15		(Reserved)	This is a reserved bit. Always set this bit to "0."
14	ExR	External request mode	External Request Mode (initial value: 0)
		1	Selects a transfer request mode.
			1: External transfer request (interrupt request or external DREQn request)
			0: Internal transfer request (software initiated)
13	PosE	Positive edge	Positive Edge (initial value: 0)
			The effective level of the transfer request signal INTDREQn or DREQn is
			specified. This function is valid only if the transfer request is an external
			transfer request (if the ExR bit is 1). If it is an internal transfer request (if the ExP bit is 0), the PoeF value is ignored. Pagenese the $\overline{\text{INTDREOP}}$ and
			the ExR bit is 0), the PosE value is ignored. Because the INTDREQn and $\overline{\text{DREQn}}$ signals are active at "L" level, make sure that this PosE bit is set
			to "0."
			1: Setting prohibited
			0: The falling edge of the INTDREQn or DREQn signal or the "L" level is
			effective. The DACKn is active at "L" level.
12	Lev	Level mode	Level Mode (initial value: 0)
			Specifies which is used to recognize the external transfer request, signal
			level or signal change. This setting is valid only if a transfer request is the external transfer request (if the ExR bit is 1). If the internal transfer
			request is specified as a transfer request (if the ExR bit is 0), the value of
			the Lev bit is ignored. Because the INTDREQn signal is active at "L"
			level, make sure that you set the Lev bit to "1." The state of active DREQn
			is determined by the Lev bit setting.
			1: Level mode The level of the DREQn signal is recognized as a data transfer request.
			(The "L" level is recognized if the PosE bit is 0.
			0: Edge mode
			A change in the $\overline{\text{DREQn}}$ signal is recognized as a data transfer request.
			(A falling edge is recognized if the PosE bit is 0.)
11	SReq	Snoop request	Snoop Request (initial value: 0)
			The use of the snoop function is specified by asserting the bus control request mode. If the snoop function is used, the snoop function of the
			TX19A processor core is enabled and the DMAC can use the data bus of
			the TX19A processor core. If the snoop function is not used, the snoop
			function of the TX19A processor core does not work.
			1: Use snoop function (SREQ)
			0: Do not use snoop function (GREQ)
10	RelEn	Bus control release	Release Request Enable (initial value: 0)
		request enable	Acknowledgment of the bus control release request made by the TX19A
			processor core is specified. This function is valid only if GREQ is generated. If SREQ is generated, the TX19A processor core cannot make a
			bus control release request and, therefore, this function cannot be used.
			1: The bus control release request is acknowledged if the DMAC has
			control of the bus. If the TX19A processor core issues a bus control
			release request, the DMAC relinquishes control of the bus to the
			<ul><li>TX19A processor core during a pause in bus operation.</li><li>0: The bus control release request is not acknowledged.</li></ul>
9	SIO	Source I/O	Source Type: I/O (initial value: 0)
7	510		Specifies the source device.
			1: I/O device
			0: Memory
		1	0. 11101101 y

# Fig. 10.3.2 Channel Control Register (CCRn) (2/3)

Bit	Mnemonic	Field name	Description
8:7	SAC	Source address count	Source Address Count (initial value: 00)
			Source Address Count (initial value: 00)
			Specifies the manner of change in a source address.
			1x: Address fixed
			01: Address decrease
			00: Address increase
6	DIO	Destination I/O	Destination Type: I/O (initial value: 0)
			Specifies a destination device.
			1: I/O device
			0: Memory
5:4	DAC	Destination address	Destination Address Count (initial value: 00)
		count	Specifies the manner of change in a destination address.
			1x: Address fixed
			01: Address decrease
			00: Address increase
3:2	TrSiz	Transfer unit	Transfer Size (initial value: 00)
			Specifies the amount of data to be transferred in response to one transfer
			request.
			11: 8 bits (1 byte)
			10: 16 bits (2 bytes)
			0x: 32 bits (4 bytes)
1:0	DPS	Device port size	Device Port Size (initial value: 00)
			Specifies the bus width of an I/O device designated as a source or
			destination device.
			11: 8 bits (1 byte)
			10: 16 bits (2 bytes)
			0x: 32 bits (4 bytes)

Fig. 10.3.2 Channel Control Register (CCRn) (3/3)

(Note 1) The CCRn register setting must be completed before the DMAC is put into a standby mode.

(Note 2) When accessing the internal I/O or transferring data by DMA in response to the DREQ pin request, make sure that you set the transfer unit <TrSiz> and the device port size <DPS> to the same size.

(Note 3) In executing memory-to-memory data transfer, a value set in DPS becomes invalid.

# 10.3.4 Channel Status Registers (CSRn) (n=0 through 7)

Bit	Mnemonic	Field name	Description
31	Act	Channel active	Channel Active (initial value: 0)
			Indicates whether the channel is in a standby mode:
			1: In a standby mode
			0: Not in a standby mode
23	NC	Normal completion	Normal Completion (initial value: 0)
			Indicates normal completion of channel operation. If an interrupt at normal completion is permitted by the CCR register, the DMAC requests an interrupt when the NC bit becomes 1.
			This setting can be cleared by writing 0 to the NC bit. If a request for an interrupt at normal completion was previously issued, the request is canceled if the NC bit becomes 0.
			If an attempt is made to set the Str bit to 1 when the NC bit is 1, an error occurs. To start the next transfer, the NC bit must be cleared to 0. A write of 1 will be ignored.
			1: Channel operation has been completed normally.
			0: Channel operation has not been completed normally

Fig. 10.3.4 Channel Status Registers (CSRn) (1/2)

Bit	Mnemonic	Field name	Description	
22	AbC	Abnormal completion	Abnormal Completion (initial value: 0)	
			Indicates abnormal completion of channel operation. If an interrupt at abnormal completion is permitted by the CCR register, the DMAC requests an interrupt when the AbC bit becomes 1.	
			This setting can be cleared by writing 0 to the AbC bit. If a request for an interrupt at abnormal completion was previously issued, the request is canceled if the AbC bit becomes 0. Additionally, if the AbC bit is cleared to 0, each of the BES, BED and Conf bits are cleared to 0.	
			If an attempt is made to set the Str bit to 1 when the AbC bit is 1, an error occurs. To start the next transfer, the AbC bit must be cleared to 0. A write of 1 will be ignored.	
			1: Channel operation has been completed abnormally.	
			0: Channel operation has not been completed abnormally.	
21		(Reserved)	This is a reserved bit. Always set this bit to "0."	
20	BES	Source bus error	Source Bus Error (initial value: 0)	
			1: A bus error has occurred when the source was accessed.	
			0: A bus error has not occurred when the source was accessed.	
19	BED	Destination bus error	Destination Bus Error (initial value: 0)	
			1: A bus error has occurred when the destination was accessed.	
			0: A bus error has not occurred when the destination was accessed.	
18	Conf	Configuration error	Configuration Error (initial value: 0)	
			1: A configuration error has occurred.	
			0: A configuration error has not occurred.	
2:0	_	(Reserved)	These three bits are reserved bits. Always set them to "0."

Bit	Mnemonic	Field name	Description
31:0	DOT	Data on transfer	Data on Transfer (initial value: 0) Data that is read from the source in a dual-address data transfer mode.

Fig. 10.3.9 Data Holding Register (DHR)

#### 10.4 Functions

#### 10.4.1 Overview

The DMAC is a 32-bit DMA controller capable of transferring data in a system using the TX19A processor core at high speeds without routing data via the core.

#### (1) Source and destination

The DMAC handles data transfers from memory to memory and between memory and an I/O device. A device from which data is transferred is called a source device and a device to which data is transferred is called a destination device. Both memory and I/O devices can be designated as a source or destination device. The DMAC supports data transfers from memory to I/O devices, from I/O devices to memory, and from memory to memory, but not between I/O devices.

The differences between memory and I/O devices are in the way they are accessed. When accessing an I/O device, the DMAC asserts a DACKn signal. Because there is only one line per channel that carries a DACKn signal, the number of I/O devices accessible during data transfer is limited to one. Therefore, data cannot be transferred between I/O devices.

An interrupt factor can be attached to a transfer request to be sent to the DMAC. If an interrupt factor is generated, the interrupt controller (INTC) issues a request to the DMAC (the TX19A processor core is not notified of the interrupt request. For details, see description on Interrupts.). The request issued by the INTC is cleared by the DACKn signal. Therefore, if an I/O device is designated as a device to which data is to be transferred, a request made to the DMAC is cleared after completion of the data transfer (transfer of the amount of data specified by TrSiz). On the other hand, during memory-to-memory transfers, the DACKn signal is asserted only when the number of bytes transferred (value set in the BCRn register) becomes "0." Therefore, one transfer request allows data to be transferred successively without a pause.

For example, if data is transferred between a internal I/O and the internal (external) memory of the TMP19A64, a request made by the internal I/O to the DMAC is cleared after completion of each data transfer and the transfer operation is always put in a standby mode for the next transfer request if the number of bytes transferred (value set in the BCRn register) does not become "0." Therefore, the DMA transfer operation continues until the value of the BCRn register becomes "0."

(2) Bus control arbitration (bus arbitration)

In response to a transfer request made inside the DMAC, the DMAC requests the TX19A processor core to arbitrate bus control authority. When a response signal is returned from the core, the DMAC acquires bus control authority and executes a data transfer bus cycle.

In acquiring bus control for the DMAC, use or nonuse of the data bus of the TX19A processor core can be specified; specifically either snoop mode or non-snoop mode can be specified for each channel by using bit 11 (SReq) of the CCRn register.

There are cases in which the TX19A processor core requests the release of bus control authority. Whether or not to respond to this request can be specified for each channel by using the bit 10 (RelEn) of the CCRn register. However, this function can only be used in non-snoop mode (GREQ). In snoop mode (SREQ), the TX19A processor core cannot request the release of bus control and, therefore, this function cannot be used.

When there are no more transfer requests, the DMAC releases control of the bus.

(Note 1) When the DMAC is acquiring bus control authority,  $\overline{\text{NMI}}$  is put on hold.

- (Note 2) Do not bring the TX19A to a halt when the DMAC is in operation.
- (Note 3) To put the TX19A into IDLE (doze) mode when the snoop function is being used, you must first stop the DMAC.

#### (3) Transfer request modes

Two transfer request modes are used for the DMAC: an internal transfer request mode and an external transfer request mode.

In the internal transfer request mode, a transfer request is generated inside the DMAC. Setting a start bit (Str bit of the channel control register CCRn) in the internal register of the DMAC to "1" generates a transfer request, and the DMAC starts to transfer data.

In the external transfer request mode, after a start bit is set to "1," a transfer request is generated when a transfer request signal  $\overline{\text{INTDREQn}}$  output by the INTC is input, or when a transfer request signal  $\overline{\text{DREQn}}$  output by an external device is input. For the DMAC, two modes are provided: the level mode in which a transfer request is generated when the "L" level of the  $\overline{\text{INTDREQn}}$  signal is detected and a mode in which a transfer request is generated when the falling edge or "L" level of the  $\overline{\text{DREQn}}$  signal is detected.

(4) Address mode

For the DMAC of the TMP19A64, only one address mode is provided: a dual address mode. A single address mode is not available.

In the dual address mode, data can be transferred from memory to memory and between memory and an I/O device. Source and destination device addresses are output by the DMAC. To access an I/O device, the DMAC asserts the DACKn signal. In the dual address mode, two bus operations, a read and a write, are executed. Data that is read from a source device for transfer is first put into the data holding register (DHR) inside the DMAC and then written to a destination device.

(5) Channel operation

The DMAC has eight channels (channels 0 through 7). A channel is activated and put into a standby mode by setting a start (Str) bit in the channel control register (CCRn) to "1."

If a transfer request is generated when a channel is in a standby mode, the DMAC acquires bus control authority and transfers data. If there is no transfer request, the DMAC releases bus control authority and goes into a standby mode. If data transfer has been completed, a channel is put in an idle state. Data transfer is completed either normally or abnormally (e.g. occurrence of errors). An interrupt signal can be generated upon completion of data transfer.

Fig. 10.4.1 shows the state transitions of channel operation.

Fig. 10.4.1 Channel Operation State Transition

(6) Combinations of transfer modes

The DMAC can transfer data by combining each transfer mode as follows:

Transfer request	Edge/level	Address mode	Transfer devices
Internal			Memory $\rightarrow$ memory
	"L" level		Memory $\rightarrow$ memory
External	(INTDREQn)		Memory $\rightarrow$ I/O
		Dual	$I/O \rightarrow memory$
	$\frac{\text{"L" level}}{(\overline{\text{DREQn}})}$	Duai	Memory $\rightarrow$ memory
External	Falling edge		Memory $\rightarrow$ I/O
	(DREQn)		$I/O \rightarrow$ memory

(7) Address changes

Address changes are broadly classified into three types: increases, decreases and fixed. The type of address change can be specified for each source and destination address by using SAC and DAC in the CCRn register. For a memory device, an increase, decrease or fixed can be specified. For an I/O device, however, only "fixed" can be specified. If an I/O device is selected as a source or destination device, SAC or DAC in the CCRn register must be set to "fixed."

If address increase or decrease is selected, the bit position for counting can be specified using SACM or DACM in the DTCRn register. To specify the bit position for counting a source address, SACM must be used, while DACM must be used to specify the bit position for a destination address. Any of the bits 0, 4, 8, 12 and 16 can be specified as the bit position for address counting. If 0 is selected, an address normally increases or decreases. By selecting bits 4, 8, 12 or 16, it is possible to increase or decrease an address irregularly.

Examples of address changes are shown below.

Example 1: Monotonic increase for a source device and irregular increase for a destination device

SAC: Address increase DAC: Address increase TrSiz: Transfer unit 32 bits Source address: 0xA000_1000				
Destination address: 0xB000_0000				
SACM: 000 $\rightarrow$ counting to begin from bit 0 of the address counter				
DACM: 001 $\rightarrow$ counting to begin from bit 4 of the address counter				
1st	Source 0xA000_1000	Destination 0xB000_0000		
2nd	0xA000_1001	0xB000_0010		
3rd	0xA000_1002	0xB000_0020		
4th	0xA000_1003	0xB000_0030		

SAC: Address decrease DAC: Address decrease TrSiz: Transfer unit 16 bits Source address: Initial value  $0xA000_1000$ Destination address:  $0xB000_0000$ SACM: 010  $\rightarrow$  counting to begin from bit 8 of the address counter DACM: 000  $\rightarrow$  counting to begin from bit 0 of the address counter

Example 2: Irregular decrease for a source device and monotonic decrease for a destination device

Source	Destination

1st	0xA000_1000	0xB000_0000
2nd	0x9FFF_FF00	0xAFFF_FFFE
3rd	0x9FFF_FE00	0xAFFF_FFFC
4th	0x9FFF_FD00	0xAFFF_FFFA

#### 10.4.2 Transfer Request

For the DMAC to transfer data, a transfer request must be issued to the DMAC. There are two types of transfer request: an internal transfer request and an external transfer request. Either of these transfer requests can be selected and specified for each channel.

Whichever is selected, the DMAC acquires bus control authority and starts to transfer data if the transfer request is generated after the start of channel operation.

• Internal transfer request

If the Str bit of CCR is set to "1" when the ExR bit of CCRn is "0," a transfer request is generated immediately. This transfer request is called an internal transfer request.

The internal transfer request is valid until the channel operation is completed. Therefore, data can be transferred continuously if either of two events shown below does not occur:

- * A transition to a channel of higher priority
- * A shift of bus control authority to another bus master of higher priority

In the case of the internal transfer request, data can only be transferred from memory to memory.

• External transfer request

If the ExR bit of CCRn is "1," setting the Str bit of CCR to "1" allows a channel to go into a standby mode. The INTC or an external device then generates the  $\overline{\text{INTDREQn}}$  or  $\overline{\text{DREQn}}$  signal for this channel to notify the DMAC of a transfer request, and a transfer request is generated. This transfer request is called an external transfer request. In the case of the external transfer request, data can be transferred from memory to memory and between memory and an I/O device.

The TMP19A64 recognizes the transfer request signal by detecting the "L" level of the INTDREQn signal or by detecting the falling edge or "L" level of the DREQn signal.

The unit of data to be transferred in response to one transfer request is specified in the TrSiz field of CCRn, and 32, 16 or 8 bits can be selected.

Transfer requests using INTDREQn and DREQn are described in detail on the next page.

① A transfer request made by the interrupt controller (INTC)

A transfer request made by the interrupt controller is cleared using the DACKn signal. This DACKn signal is asserted only if a bus cycle for an I/O device or the number of bytes (value set in the BCRn register) transferred from memory to memory becomes "0." Therefore, if data is transferred between memory and an I/O device, the amount of data specified by TrSiz is transferred only once because INTDREQn is cleared upon completion of one data transfer from one transfer request. On the other hand, if data is transferred from memory to memory, it can be transferred successively in response to a transfer request because INTDREQn is not cleared until the number of bytes transferred (value set in the BCRn register) becomes "0."

Note that if the DMAC acknowledges an interrupt set in INTDREQn and if this interrupt is cleared by the INTC before DMA transfer begins, there is a possibility that DMA transfer might be executed once after the interrupt is cleared, depending on the timing.

② A transfer request made by an external device

External pins ( $\overline{DREQ2}$  and  $\overline{DREQ3}$ ) are internally wired to allow them to function as pins of the port F and port J. These pins can be selected by setting the function control registers PFFC and PJFC to an appropriate setting. If both ports are set to use the DMAC function, the port F is given priority in using the DMAC function.

In the edge mode, the DREQn signal must be deasserted and then asserted for each transfer request to create an effective edge. In the level mode, however, successive transfer requests can be recognized by maintaining an effective level. In memory-to-memory transfer, only the "L" level mode can be used. In I/O-to-memory transfer, only the falling edge mode can be used.

#### - Level mode

In the level mode, the DMAC detects the "L" level of the  $\overline{DREQn}$  signal upon the rising of the internal system clock. If it detects the "L" level of the  $\overline{DREQn}$  signal when a channel is in a standby mode, it goes into transfer mode and starts to transfer data. To use the  $\overline{DREQn}$  signal at an active level, the PosE bit (bit 13) of the CCRn register must be set to "0." The  $\overline{DACKn}$  signal is active at the "L" level, as in the case of the  $\overline{DREQn}$  signal.

If an external circuit asserts the  $\overline{DREQn}$  signal, the  $\overline{DREQn}$  signal must be maintained at the "L" level until the  $\overline{DACKn}$  signal is asserted. If the  $\overline{DREQn}$  signal is deasserted before the  $\overline{DACKn}$  signal is asserted, a transfer request may not be recognized.

If the DREQn signal is not at the "L" level, the DMAC judges that there is no transfer request, and starts a transfer operation for other channels or releases bus control authority and goes into a standby mode.

The unit of a transfer request is specified in the TrSiz field (<bit3:2>) of the CCRn register.

Fig. 10.4.2.1 Transfer Request Timing (Level Mode)

Edge mode

In the edge mode, the DMAC detects the falling edge of the  $\overline{DREQn}$  signal. If it detects the falling edge of the  $\overline{DREQn}$  signal upon the rising of the internal system clock (the case in which the "L" level is detected upon the rising of the system clock although it was not detected upon the rising of the previous system clock) when a channel is in a standby mode, it judges that there is a transfer request, goes into transfer mode, and starts a transfer operation. To detect the falling edge of the  $\overline{DREQn}$  signal, the PosE bit (bit 13) of the CCRn register must be set to "0," and the Lev bit (bit 12) must also be set to "0." The  $\overline{DACKn}$  signal is active at the "L" level.

If the falling edge of the  $\overline{\text{DREQn}}$  signal is detected after the  $\overline{\text{DACKn}}$  signal is asserted, the next data is transferred without a pause.

If there is no falling edge of the  $\overline{DREQn}$  signal after the  $\overline{DACKn}$  signal is asserted, the DMAC judges that there is no transfer request, and starts a transfer operation for other channels or goes into a standby mode after releasing bus control authority.

The unit of a transfer request is specified in the TrSiz field (<bit3:2>) of the CCRn register.

Fig. 10.4.2.2 Transfer Request Timing (Edge Mode)

#### 10.4.3 Address Mode

In the address mode, whether the DMAC executes data transfers by outputting addresses to both source and destination devices or it does by outputting addresses to either a source device or a destination device is specified. The former is called the dual address mode, and the latter is called the single address mode. For TMP19A64, only the dual address mode is available.

In the dual address mode, The DMAC first performs a read of the source device by storing the data output by the source device in one of its registers (DHR). It then executes a write on the destination device by writing the stored data to the device, thereby completing the data transfer.

Fig. 10.4.3.1 Basic Concept of Data Transfer in the Dual Address Mode

The unit of data to be transferred by the DMAC is the amount of data (32, 16 or 8 bits) specified in the TrSiz field of the CCRn. One unit of data is transferred each time a transfer request is acknowledged.

In the dual address mode, the unit of data is read from the source device, put into the DHR and written to the destination device.

Access to memory takes place when the specified unit of data is transferred. If access to external memory takes place, 16-bit access takes place twice if the unit of data is set to 32 bits and if the bus width set in the CS wait controller is 16 bits. Likewise, if the unit of data is set to 32 bits and if the bus width set in the CS wait controller is 8 bits, 8-bit access takes place four times.

If data is to be transferred from memory to an I/O device or from an I/O device to memory, the unit of data to be transferred must be specified and, at the same time, the bus width of an I/O device (device port size) must be specified in the DPS field of the CCRn (32, 16 or 8 bits).

If the unit of data to be transferred is equal to a device port size, a read or write is executed once for an I/O device.

If a device port size is smaller than the unit of data to be transferred, the DMAC performs a read or write for an I/O device more than once. For example, if the unit of data to be transferred is 32 bits and if data is transferred from an I/O device whose device port size is 8 bits to memory, 8 bits of data are read from an I/O device four consecutive times and stored in the DHR. This 32-bit data is then written to memory all at once (twice if the data is written to external memory and if the bus width is 16 bits).

An address change occurs by the amount defined as the unit of data to be transferred. The BCRn value also changes by the same amount. A device port size must not be larger than the unit of data to be transferred. The relationships between units of data to be transferred and device port sizes are summarized in Table 10.4.3.2.

TrSiz	DPS	Bus operations performed on I/O device
0x (32 bits)	0x (32 bits)	Once
0x (32 bits)	10 (16 bits)	Twice
0x (32 bits)	11 (8 bits)	4 times
10 (16 bits)	0x (32 bits)	Setting prohibited
10 (16 bits)	10 (16 bits)	Once
10 (16 bits)	11 (8 bits)	Twice
11 (8 bits)	0x (32 bits)	Setting prohibited
11 (8 bits)	10 (16 bits)	Setting prohibited
11 (8 bits)	11 (8 bits)	Once

Table 10.4.3.2 Units of Data to Be Transferred and Device Port Sizes (Dual Address Mode)

#### 10.4.4 Channel Operation

A channel is activated if the Str bit of the CCRn of a channel is set to "1." If a channel is activated, an activation check is conducted and if no error is detected, the channel is put into a standby mode.

If a transfer request is generated when a channel is in a standby mode, the DMAC acquires bus control authority and starts to transfer data.

Channel operation is completed either normally or abnormally (forced termination or occurrence of an error). Either normal completion or abnormal completion is indicated to the CSRn.

#### Start of channel operation

A channel is activated if the Str bit of the CCRn is set to "1."

When a channel is activated, a configuration error check is conducted and if no error is detected, the channel is put into a standby mode. If an error is detected, the channel is deactivated and this state of completion is considered to be abnormal completion. When a channel goes into a standby mode, the Act bit of the CSRn of that channel becomes "1."

If a channel is programmed to start operation in response to an internal transfer request, a transfer request is generated immediately and the DMAC acquires bus control authority and starts to transfer data. If a channel is programmed to start operation in response to an external transfer request, the DMAC acquires bus control authority after INTDREQn or DREQn is asserted, and starts to transfer data.

#### Completion of channel operation

A channel completes operation either normally or abnormally and either one of these states is indicated to the CSRn.

If an attempt is made to set the Str bit of the CCRn register to "1" when the NC or AbC bit of the CSRn register is "1," channel operation does not start and the completion of operation is considered to be abnormal completion.

Normal completion

Channel operation is considered to have been completed normally in the case shown below. For channel operation to be considered to have been completed normally, the transfer of a unit of data (value specified in the TrSiz field of CCRn) must be completed successfully.

• When the contents of BCRn become 0 and data transfer is completed

Abnormal completion

Cases of abnormal completion of DMAC operation are as follows:

• Completion due to a configuration error

A configuration error occurs if there is a mistake in the DMA transfer setting. Because a configuration error occurs before data transfer begins, values specified in SARn, DARn and BCRn remain the same as when they were initially specified. If channel operation is completed abnormally due to a configuration error, the AbC bit of the CSRn is set to "1," along with the Conf bit. Causes of a configuration error are as follows:

- Both SIO and DIO were set to "1."
- The Str bit of CCRn was set to "1" when the NC bit or AbC bit of CSRn was "1."
- A value that is not an integer multiple of the unit of data was set for BCRn.
- A value that is not an integer multiple of the unit of data was set for SARn or DARn.
- A prohibited combination of a device port size and a unit of data to be transferred was set.
- The Str bit of CCRn was set to "1" when the BCRn value was "0."

• Completion due to a bus error

If the DMAC operation has been completed abnormally due to a bus error, the AbC bit of CSRn is set to "1" and the BES or BED bit of CSRn is set to "1."

A bus error was detected during data transfer.

# (Note) If the DMAC operation has been completed abnormally due to a bus error, BCR, SAR and DAR values cannot be guaranteed. If a bus error persists, refer to 21. "List of Functional Registers" which appear later in this document.

#### 10.4.5 Order of Priority of Channels

Concerning the eight channels of the DMAC, the smaller the channel number assigned to each channel, the higher the priority. If a transfer request is generated to channels 0 and 1 simultaneously, a transfer request for channel 0 is processed with higher priority and the transfer operation is performed accordingly. When the transfer request for channel 0 is cleared, the transfer operation for channel 1 is performed if the transfer request still exists (An internal transfer request is retained if it is not cleared. The interrupt controller retains an external transfer request if the active state for an interrupt request assigned to DMA requests in the interrupt controller is set to level mode. If the active state for an interrupt request state for an interrupt request is not cleared is not cleared to DMA requests in the interrupt controller is set to level mode. If the active state for an interrupt request assigned to DMA requests in the interrupt controller is set to level mode. If the active state for an interrupt request assigned to DMA requests in the interrupt controller is set to level mode. If the active state for an interrupt request assigned to DMA requests in the interrupt controller is set to level mode. If the active state for an interrupt request assigned to DMA requests in the interrupt controller is set to level mode. If the active state for an interrupt request assigned to DMA requests in the interrupt controller is set to level mode. If the active state for an interrupt request assigned to DMA requests in the interrupt controller is set to level mode.

If a transfer request is generated when data is being transferred through channel 1, a channel transition occurs at channel 0, that is, data transfer through channel 1 is temporarily suspended and data transfer through channel 0 is started. When the transfer request for channel 0 is cleared, data transfer through channel 1 resumes.

Channel transitions occur upon the completion of data transfers (when the writing of all data in the DHR has been completed).

#### Interrupts

Upon completion of a channel operation, the DMAC can generate interrupt requests (INTDMAn: DMA transfer completion interrupt) to the TX19A processor core with two types of interrupts available: a normal completion interrupt and an abnormal completion interrupt.

• Normal completion interrupt

If a channel operation is completed normally, the NC bit of CSRn is set to "1." If a normal completion interrupt is authorized for the NIEn bit of the CCRn, the DMAC requests the TX19A processor core to authorize an interrupt.

• Abnormal completion interrupt

If a channel operation is completed abnormally, the AbC bit of CSRn is set to "1." If an abnormal completion interrupt is authorized for the AbIEn bit of the CCRn, the DMAC requests the TX19A processor core to authorize an interrupt.

#### 10.5 Timing Diagrams

DMAC operations are synchronous to the rising edges of the internal system clock.

#### 10.5.1 Dual Address Mode

• Memory-to-memory transfer

Fig. 10.5.1.1 shows an example of the timing with which 16-bit data is transferred from one external memory (16-bit width) to another (16-bit width). Data is actually transferred successively until BCRn becomes "0."

Fig. 10.5.1.1 Dual Address Mode (Memory-to-Memory)

• Memory-to-I/O device transfer

Fig. 10.5.1.2 shows an example of the timing with which data is transferred from memory to an I/O device if the unit of data to be transferred is set to 16 bits and if the device port size is set to 8 bits.

• I/O device-to-memory transfer

Fig. 10.5.1.3 shows an example of the timing with which data is transferred from an I/O device to memory if the unit of data to be transferred is set to 16 bits and if the device port size is set to 8 bits.

Fig. 10.5.1.3 Dual Address Mode (I/O Device-to-Memory)

#### 10.5.2 DREQn-Initiated Transfer Mode

• Data transfer from internal RAM to external memory (multiplexed bus, 5-wait insertion, level mode)

Fig. 10.5.2.1 shows two timing cycles in which 16-bit data is transferred twice from internal RAM to external memory (16-bit width).

#### 10.6 Case of Data Transfer

The settings described below relate to a case in which serial data received (SCnBUF) is transferred to the internal RAM by DMA transfer.

DMA (ch.0) is used to transfer data. The DMA0 is activated by a receive interrupt generated by SIO1.

<DMA setting>

- Channel used: 0
- Source address: SC1BUF
- Destination: (Physical address) 0xFFFF_9800
- Number of bytes transferred: 256 bytes

#### <Serial channel setting>

- Data length 8 bits: UART
- Serial channel: ch 1
- Transfer rate: 9600 bps

#### <SIO ch.1 setting>

IMC4	$\leftarrow$	0xxxxx_xx70	/* assigned to DMC0 activation factor * /
INTCLR	$\leftarrow$	0x40	/* IVR [9:4], INTRX1 interrupt factor * /
SC1MOD0	$\leftarrow$	0x29	/* UART mode, 8-bit length, baud rate generator * /

#### TOSHIBA

### 11. 16-bit Timer/Event Counters (TMRBs)

Each of the eleven channels (TMRB0 through TMRBA) has a multi-functional, 16-bit timer/event counter. TMRBs operate in the following four operation modes:

- 16-bit interval timer mode
- 16-bit event counter mode
- 16-bit programmable square-wave output (PPG) mode
- Two-phase pulse input counter mode (quad-speed and TMRBA)

The use of the capture function allows TMRBs to operate in three other modes:

- Frequency measurement mode
- Pulse width measurement mode
- Time difference measurement mode

Each channel consists of a 16-bit up-counter, two 16-bit timer registers (one of which is double-buffered), two 16-bit capture registers, two comparators, a capture input control, a timer flip-flop and its associated control circuit.

Each channel (TMRB0 through TMRBA) functions independently and while the channels operate in the same way, there are differences in their specifications as shown in Table 11.1 and the two-phase pulse count function. Therefore, the operational descriptions here are for TMRB0 only and for the two-phase pulse count function TMRBA only.

#### 11.1 Block Diagram of Each Channel

(Note) TMRB2 through TMRB9 have no external clock and capture trigger input functions.

Fig. 11.1.1 TMRB0 Block Diagram (Same for Channels 1 through 9)

Fig. 11.1.2 TMRBA Block Diagram

#### 11.2 Description of Operations for Each Circuit

#### 11.2.1 Prescaler

There is a 5-bit prescaler for acquiring the TMRB0 source clock. The prescaler input clock  $\phi$ T0 is fperiph/2, fperiph/4, fperiph/8 or fperiph/16 selected by SYSCR0<PRCK1:0> in the CG. The peripheral clock, fperiph, is either fgear, a clock selected by SYSCR1<FPSEL> in the CG, or fc, which is a clock before it is divided by the clock gear.

The operation or the stoppage of a prescaler is set with TB0RUN<TB0PRUN> where writing "1" starts counting and writing "0" clears and stops counting. Table 11.2.1 shows prescaler output clock resolutions.

Release	Clock gear	Select prescaler	Presc	aler output clock res	solutions
peripheral clock <fpsel></fpsel>	value <gear2:0></gear2:0>	clock <prck1 0="" :=""></prck1>	<b>φ</b> T1	φT4	φT16

Table 11.2.1 Prescaler Output Clock Resolutions

(Note 1) The prescaler output clock φTn must be selected so that φTn<fsys/2 is satisfied (so that φTn is slower than fsys/2).

- (Note 2) Do not change the clock gear while the timer is operating.
- (Note 3) "—" denotes a setting prohibited.

#### 11.2.2 Up-counter (UC0) and Up-counter Capture Registers (TB0UCL, TB0UCH)

This is the 16-bit binary counter that counts up in response to the input clock specified by TB0MOD<TB0CLK1:0>.

UC0 input clock can be selected from either three types -  $\phi$ T0,  $\phi$ T2 and  $\phi$ T8 - of prescaler output clock or the external clock of the TB0IN0 pin. For UC0, start, stop and clear are specified by TB0RUN<TB0RUN> and if UC0 matches the TB0RG1H/L timer register, it is cleared to "0" if the setting is "clear enable." Clear enable/disable is specified by TB0MOD<TB0CLE>.

If the setting is "clear disable," the counter operates as a free-running counter.

The current count value of the UC0 can be captured by reading the TB0UCL and TB0UCH registers.

### Note Make sure that reading is performed in the order of low-order bits followed by high-order bits.

If UC0 overflow occurs, the INTTB01 overflow interrupt is generated.

TMRBA have the two-phase pulse input count function. The two-phase pulse count mode is activated by TBARUN<TBAUDCE>. This counter serves as the up-and-down counter, and is initialized to 0x7FFF. If a counter overflow occurs, the initial value 0x0000 is reloaded. If a counter underflow occurs, the initial value 0xFFFF is reloaded. When the two-phase pulse count mode is not active, the counter counts up only.

#### 11.2.3 Timer Registers (TB0RG0H/L, TB0RG1H/L)

These are 16-bit registers for specifying counter values and two registers are built into each channel. If a value set on this timer register matches that on a UC0 up-counter, the match detection signal of the comparator becomes active.

To write data to the TB0RG0H/L and TB0RG1H/L timer registers, either a 2-byte data transfer instruction or a 1-byte data transfer instruction written twice in the order of low-order 8 bits followed by high-order 8 bits can be used.

TB0RG0 of this timer register is paired with register buffer 0 - a double-buffered configuration. TB0RG0 uses TB0RUN<TB0RDE> to control the enabling/disabling of double buffering so that if  $\langle TB0RDE \rangle =$  "0," double buffering is disabled and if  $\langle TB0RDE \rangle =$  "1," it is enabled. If double buffering is enabled, data is transferred from register buffer 0 to the TB0RG0 timer register when there is a match between UC0 and TB0RG1.

The values of TB0RG0 and TB0RG1 become undefined after a reset so to use a 16-bit timer, it is necessary to write data to them beforehand. A reset initializes TB0RUN <TB0RDE> to "0" and sets double buffering to "disable." To use double buffering, write data to the timer register, set <TB0RDE> to "1" and then write the following data to the register buffers.

TB0RG0 and the register buffers are assigned to the same address:  $0xFFFF_F18A/0xFFFF_F18B$ . If  $\langle TB0RDE \rangle = "0,"$  the same value is written to TB0RG0 and each register buffer; if  $\langle TB0RDE \rangle = "1,"$  the value is only written to each register buffer. To write an initial value to the timer register, therefore, the register buffers must be set to "disable."

#### 11.2.4 Capture Registers (TB0CP0H/L, TB0CP1H/L)

To read data from the capture register, use 1-byte data transfer instruction twice and **make sure that** reading is performed in the order of low-order bits followed by high-order bits.

(Don't use 2-byte transfer instruction for data reading.)

#### 11.2.5 Capture

This is a circuit that controls the timing of latching values from the UC0 up-counter into the TB0CP0 and TB0CP1 capture registers. The timing with which to latch data is specified by TB0MOD <TB0CPM1:0>.

Software can also be used to import values from the UC0 up-counter into the capture register; specifically, UC0 values are taken into the TB0CP0 capture register each time "0" is written to TB0MOD<TB0CP0>. To use this capability, the prescaler must be running (TB0RUN<TB0PRUN> = "1").

In the two-phase pulse count mode (TMRBA), the counter value is captured by using software.

(Note 1) Although a read of low-order 8 bits in the capture register suspends the capture operation, it is resumed by successively reading high-order 8 bits.

(Note 2) If the timer stops after a read of low-order 8 bits, the capture operation remains suspended even after the timer restarts. Please ensure that the timer is not stopped after a read of low-order 8 bits.

#### 11.2.6 Comparators (CP0, CP1)

These are 16-bit comparators for detecting a match by comparing set values of the UC0 up-counter with set values of the TB0RG0 and TB0RG1 timer registers. If a match is detected, INTTB0 is generated.

#### 11.2.7 Timer Flip-flop (TB0FF0)

The timer flip-flop (TB0FF0) is reversed by a match signal from the comparator and a latch signal to the capture registers. It can be enabled or disabled to reverse by setting the TB0FFCR<TB0C1T1, TB0C0T1, TB0E1T1, TB0E0T1>.

The value of TB0FF0 becomes undefined after a reset. The flip-flop can be reversed by writing "00" to TB0FFCR<TB0FF0C1:0>. It can be set to "1" by writing "01," and can be cleared to "0" by writing "10."

The value of TB0FF0 can be output to the timer output pin, TB0OUT (shared with PA2). To enable timer output, the port A related registers PACR and PAFC must be programmed beforehand.

#### 11.3 Register Description

(0xFFFF_F1x0)

		7	6	5	4	3	2	1	0

	Function	TMRBn operation 0: Disable 1: Enable	Write "0."	This can be read as "0."					

TMRBn control register (n=0 through A)

<TBnEN>: Specifies the TMRB operation. When the operation is disabled, no clock is supplied to the other registers in the TMRB module. This can reduce power dissipation. (This disables reading from and writing to the other registers.) To use the TMRB, enable the TMRB operation (set to "1") before programming each register in the TMRB module. If the TMRB operation is executed and then disabled, settings will be maintained in each register.

TB0FFCR	←	Х	Х	0	0	0	0	_	_		Disables the trigger.
TB0MOD	←	Х	Х	1	0	0	1	0	0		Designates the TB0IN0 pin input as the input clock.
TBORUN	←	0	0	0	0	_	1	Х	1		Starts TMRB0.
TB0MOD	←	Х	Х	0	0	0	1	0	0		Captures a value using software.
TB0CP0L	←	*	*	*	*	*	*	*	*		Reads the count value of low-order 8 bits.
ТВОСРОН	←	*	*	*	*	*	*	*	*		Reads the counter value of high-order 8 bits.

X; Don't care –; no change

To be used as the event counter, put the prescaler in a "RUN" state (TB0RUN<TB0PRUN> = "1").

#### 11.4.3 16-bit PPG (Programmable Square Wave) Output Mode

Square waves with any frequency and any duty (programmable square waves) can be output. The output pulse can be either low-active or high-active.

Programmable square waves can be output from the TB0OUT pin by triggering the timer flip-flop (TB0FF) to reverse when the set value of the up-counter matches the set values of the timer registers (TB0RG0H/L and TB0RG1H/L). Note that the set values of TB0RG0H/L and TB0RG1H/L must satisfy the following requirement:

(Set value of TB0RG0H/L) < (Set value of TB0RG1H/L)

Fig. 11.4.3.1 Example of Output of Programmable Square Wave (PPG)

In this mode, by enabling the double buffering of TB0RG0H/L, the value of register buffer 0 is shifted into TB0RG0H/L when the set value of the up-counter matches the set value of TB0RG1H/L. This facilitates handling of small duties.

Fig. 11.4.3.2 Register Buffer Operation

The block diagram of the 16-bit PPG (programmable square wave) output mode is shown below.

Fig. 11.4.3.3 Block Diagram of 16-bit PPG Mode

<< Example of setting of each register in the 16-bit PPG output mode >>

_		7	6	5	4	3	2	1	0

#### **11.4.4** Applications using the Capture Function

The capture function can be used to develop many applications, including those described below:

- ① One-shot pulse output triggered by an external pulse
- ② Frequency measurement
- ③ Pulse width measurement
- ④ Time difference measurement
- ① One-shot pulse output triggered by an external pulse

One-shot pulse output triggered by an external pulse is carried out as follows:

The 16-bit up-counter (UC0) is made to count up by putting it in a free-running state using the prescaler output clock. An external pulse is input through the TB0IN0 pin. A trigger is generated at the rising of the external pulse by using the capture function and the value of the up-counter is taken into the capture registers (TB0CP0H/L).

The INTC must be programmed so that an interrupt INT5 is generated at the rising of an external trigger pulse. This interrupt is used to set the timer registers (TB0RG0H/L) to the sum of the TB0CP0H/L value (c) and the delay time (d), (c + d), and set the timer registers (TB0RG1H/L) to the sum of the TB0RG0H/L values and the pulse width (p) of one-shot pulse, (c + d + p).

In addition, the timer flip-flop control registers (TB0FFCR<TB0E1T1, TB0E0T1>) must be set to "11." This enables triggering the timer flip-flop (TB0FF0) to reverse when UC0 matches TB0RG0H/L and TB6RG1H/L. This trigger is disabled by the INTTB0 interrupt after a one-shot pulse is output.

Symbols (c), (d) and (p) used in the text correspond to symbols c, d and p in Fig. 11.4.4.1.

Fig. 11.4.4.1 One-shot Pulse Output (With Delay)

#### TOSHIBA

Programming example: Output a 2-ms one-shot pulse triggered by an external pulse from the TB0IN0 pin with a 3-ms delay

IMC5 ←	X 1 1 X X X	$\left.\begin{array}{cccccccccccccccccccccccccccccccccccc$	Disables INTTB0				

#### X; Don't care —;no change

If a delay is not required, TB0FF0 is reversed when data is taken into TB0CP0H/L, and TB0RG1L/H is set to the sum of the TB0CP0H/L value (c) and the one-shot pulse width (p), (c + p), by generating the INT5 interrupt. TB0FF0 is enabled to reverse when UC0 matches with TB0RG1L/H, and is disabled by generating the INTTB0 interrupt.

#### TOSHIBA

Fig. 11.4.4.2 One-shot Pulse Output Triggered by an External Pulse (Without Delay)

② Frequency measurement

By using the capture function, the frequency of an external clock can be measured.

To measure frequency, another 16-bit timer (TMRB3) is used in combination with the 16-bit event counter mode (TMRB3 reverses TB3FFCR to specify the measurement time).

The TB0IN0 pin input is selected as the TMRB0 count clock to perform the count operation using an external input clock. TB0MOD<TB0CPM1:0> is set to "11." This setting allows a count value of the 16-bit UC0 up-counter to be taken into the capture register (TB0CP0) upon the rising of a timer flip-flop (TB3FFCR) of the 16-bit timer (TMRB3), and an UC0 counter value to be taken into the capture register (TB0CP1H/L) upon the falling of TB3FF of the 16-bit timer (TMRB3).

A frequency is then obtained from the difference between TB0CP0H/L and TB0CP1H/L based on the measurement, by generating the INTTB3 16-bit timer interrupt.

Fig. 11.4.4.3 Frequency Measurement

For example, if the set width of TB3FF level "1" of the 16-bit timer is 0.5 s and if the difference between TB0CP0H/L and TB0CP1H/L is 100, the frequency is 100 / 0.5 s = 200 Hz.

③ Pulse width measurement

By using the capture function, the "H" level width of an external pulse can be measured. Specifically, an external pulse is input through the TB0IN0 pin and the up-counter (UC0) is made to count up by putting it in a free-running state using the prescaler output clock. A trigger is generated at each rising and falling edge of the external pulse by using the capture function and the value of the up-counter is taken into the capture registers (TB0CP0H/L, TB0CP1H/L). The INTC must be programmed so that INT5 is generated at the falling edge of an external pulse input through the TB0IN0 pin.

The "H" level pulse width can be calculated by multiplying the difference between TB0CP0H/L and TB0CP1H/L by the clock cycle of an internal clock.

For example, if the difference between TB0CP0H/L and TB0CP1H/L is 100 and the cycle of the prescaler output clock is 0.5  $\mu$ s, the "H" level pulse width is 100 × 0.5  $\mu$ s = 50  $\mu$ s.

Caution must be exercised when measuring pulse widths exceeding the UC0 maximum count time which is dependant upon the source clock used. The measurement of such pulse widths must be made using software.

Fig. 11.4.4.4 Pulse Width Measurement

The "L" level width of an external pulse can also be measured. In such cases, the difference between C2 generated the first time and C1 generated the second time is initially obtained by performing the second stage of INT5 interrupt processing as shown in Fig. 11.4.4.5 and this difference is multiplied by the cycle of the prescaler output clock to obtain the "L" level width.

④ Time Difference Measurement

By using the capture function, the time difference between two events can be measured. Specifically, the up-counter (UC0) is made to count up by putting it in a free-running state using the prescaler output clock. The value of UC0 is taken into the capture register (TB0CP0H/L) at the rising edge of the TB0IN0 pin input pulse. The INTC must be programmed to generate INT5 interrupt at this time.

The value of UC0 is taken into the capture register TB0CP1H/L at the rising edge of the TB0IN1 pin input pulse. The INTC must be programmed to generate INT6 interrupt at this time.

The time difference can be calculated by multiplying the difference between TB0CP1H/L and TB0CP0H/L by the clock cycle of an internal clock.

Fig. 11.4.4.5 Time Difference Measurement

#### 11.4.5 Two-phase Pulse Input Count Mode (TMRBA)

In this mode, the counter is incremented or decremented by one depending on the state transition of the two-phase clock that is input through TBAIN0 and TBAIN1 and has phase difference. An interrupt is output when a counter overflow or underflow occurs in the up-and-down counter mode, and when the counting operation is executed.

This is the multiplication-by-4 mode in which the counter counts up/down at each count.

Fig. 11.4.5.1 Count Circuit of Two-phase Counter

#### 11.4.6 Multiplication-by-4 Mode

DOWN 1 0 0 1 1 1 1 0 0 1 0 0_ 3 2 1

#### TMRBA RUN register (TBARUN)

Fig. 11.4.6.1 Two-phase Pulse Input Count Mode Setting Register

For the sampling clock, the fifth bit <UDACK> of the TBARUN register is set to "1."

#### << Recovery from the SLEEP mode >>

The two-phase counter counts up or down depending on the SLEEP release input state.

#### ① Operation mode

Register setting determines whether the external input signals from the TBAIN0 and TBAIN1 input pins are input to the normal 16-bit timer (capture input) or the up-and-down counter.

- In the up-and-down counter mode, capture is executed by the software only. Capture at the external clock timing does not work.
- In the up-and-down counter mode, the comparator is disabled and it does not execute comparison with timer registers.
- The input clock sampling is executed by fs (32 KHz) or the high-speed clock (system clock). The maximum input frequency is 4 kHz for fs and  $\phi$ T0/4 [Hz] for the high-speed clock.

#### << How to program the up-and-down counter >>

Set the TBAMOD register <TBACLK0, TBACLK1> to "00" (prescaler OFF). Then, program the fourth bit <TBAUDCE> of the TBARUN register to determine whether to operate the counter as the up-and-down counter or as the conventional up-counter for external clock input.

TBAUDCE (Enable the up-and-down counter)	= "0": Normal 16-bit timer operation
	= "1": Up-and-down counter operation

#### ② Interrupt

In the NORMAL or SLOW mode

The INTTBA interrupt is generated by counting up or down. Reading the status register TBAST during interrupt handling allows simultaneous check for occurrences of an overflow and an underflow. If TBAST<INTTBOUFA> is "1," it indicates that an overflow has occurred. If <INTTBUDFA> is "1," it indicates that an underflow has occurred. This register is cleared after it is read. The counter becomes 0x0000 when an overflow occurs, and it becomes 0xFFFF when an underflow occurs. After that, the counter continues the counting operation.

		7	6	5	4	3	2	1	0
TBAST (0xFFFF_F1E4)	bit Symbol				INTTBUDA	INTTBUDF A	INTTBOUF A		
(0XFFFF_F1E4)	Read/Write	^	R			R		F	2
	After reset		0		0	0	0	(	)
	Function	This can be	e read as "0."		Up-and- down count 0: Not occurred 1: Occurred	Underflow 0: Not occurred 1: Occurred	Overflow 0: Not occurred 1: Occurred	This can be "0."	read as

Fig. 11.4.6.2 TMRBA Status Register

#### Note: The status is cleared after the register is read.

In the SLEEP mode

The INTTBA interrupt is enabled using the interrupt controller (INTC). The INTTBA interrupt is generated by the count-up or count-down input, and the system recovers from the SLEEP mode. Reading the status register TBAST during interrupt handling allows simultaneous check for occurrences of an overflow and an underflow

#### ③ Up-and-down counter

When the two-phase input count mode is selected (TBARUN<TBAUDCE> = "1"), the up-counter becomes the up-and-down counter and it is initialized to 0x7FFF. If a counter overflow occurs, the counter returns to 0x0000. If a counter underflow occurs, the counter returns to 0xFFFF. After that, the counter continues the counting operation. Therefore, the state can be checked by reading the counter value and the status flag TBAST after an interrupt is generated.

Sampling clock				$\prod_{i=1}^{n} \prod_{j=1}^{n} \prod_{i=1}^{n} \prod_{j=1}^{n} \prod_{j=1}^{n} \prod_{j=1}^{n} \prod_{i=1}^{n} \prod_{j=1}^{n} \prod_{j$

Up-and-down interrupt		 		ļ

# (Note 1) The up (down) count input must be set to the "H" level for the states before and after an input.

(Note 2) Reading of counter value must be executed during INTTBA interrupt handling

### 12. 32-bit Input Capture (TMRC)

TMRC consists of one channel with a 32-bit time base timer (TBT), four channels (TCCAP0 through TCCAP3) each with a 32-bit input capture register, and ten channels (TCCMP0 through TCCMP9) each with a 32-bit compare register.

Fig. 12-1 shows the TMRC block diagram.

Fig. 12.1 Timer C Block Diagram

#### 12.1 Description for Operations of Each Circuit

#### 12.2.1 Prescaler

The prescaler is provided to acquire the TMRC source clock. The prescaler input clock  $\phi$ T0 is fperiph/2, fperiph/4, fperiph/8 or fperiph/16 selected by SYSCR0<PRCK1:0> in the CG.  $\phi$ T2 through  $\phi$ T256 generated by dividing  $\phi$ T0 are available as TMRC prescaler input clocks and can be selected with TBTCR<TBTCLK3:0>.

Fperiph is either "fgear" which is a clock selected by SYSCR1<FPSEL> in the CG, or "fc" which is a clock before it is divided by the clock gear.

The operation or stoppage of the prescaler is set with TBTRUN<TBTPRUN> where writing "1" starts counting and writing "0" clears and stops counting. Table 12-1 shows the prescaler output clock resolutions.

# Table 12.1 Prescaler Output Clock Resolutions (if any of high-speed clock gears 8/8, 4/8, 2/8 and 1/8 is selected)

### (Note 1) The prescaler output clock $\phi$ Tn must be selected so that $\phi$ Tn<fsys/2 is satisfied (so that $\Phi$ Tn is slower than fsys/2).

(Note 2) Do not change the clock gear while the timer is operating.

(Note 3) "-" denotes "setting prohibited."

#### 12.2.2 Noise Removal Circuit

The noise removal circuit removes noises from an external clock source input (TBTIN) and a capture trigger input (TcnIN) of the time base timer (TBT). It can also output input signals without removing noises from them.

#### 12.2.3 32-bit Time Base Timer (TBT)

This is a 32-bit binary counter that counts up upon the rising of an input clock specified by the TBT control register TBTCR of the time base timer.

Based on the TBTCR<TBTCLK3:0> setting, an input clock is selected from external clocks supplied through the TBTIN pin and eight prescaler output clocks  $\phi$ T2,  $\phi$ T4,  $\phi$ T8,  $\phi$ T16,  $\phi$ T32,  $\phi$ T64,  $\phi$ T128, and  $\phi$ T256.

"Count," "stop" or "clear" of the up-counter can be selected with TBTRUN<TBTRUN>. When a reset is performed, the up-counter is in a cleared state and the timer is in an idle state. As counting starts, the up-counter operates in a free-running condition. As it reaches an overflow state, the overflow interrupt INTTBT is generated; subsequently, the count value is cleared to 0 and the up-counter restarts a count-up operation. INTTBT is controlled by the TCGST and TCGIM that are grouped in the same way as INTCAP0 through INTCAP3 are (see the explanation about the 32-bit capture register).

This counter can perform a read capture operation. When it is performing a read capture operation, it is possible to read a counter value by accessing the TBT read capture register (TBTRDCAP) in units of 32 bits.

However, a counter value cannot be read (captured) if the register is accessed in units of 8 or 16 bits.

#### 12.2.4 Edge Detection Circuit

By performing sampling, this circuit detects the input edge of an external capture input (TcnIN). It can be set to "rising edge," "falling edge," "both edges" or "not capture" by provisioning the capture control register CAPnCR<CPnEG1:0>. Fig. 12.2.4.1 shows capture inputs, outputs (capture factor outputs) produced by the edge detection circuit, and specific detection circuit settings.

Fig. 12.2.4.1 Capture Inputs and Capture Factor Outputs (Outputs Produced by the Edge Detection Circuit)

#### 12.2.5 32-bit Capture Register

This is a 32-bit register for capturing count values of the time base timer by using capture factors as triggers. If a capture operation is performed, the capture interrupt INTCAPn is generated. Four interrupt requests INTCAP0 through INTCAP3 are grouped into one set of interrupt requests which are then notified to the interrupt controller. Which one of interrupt requests INTCAP0 through INTCAP3 must be processed can be identified by reading the status register TCGST during interrupt processing. Additionally, it is possible to mask unnecessary interrupts by setting the interrupt mask register TCGIM to an appropriate bit setting. While a read of the capture register is ongoing, count values cannot be captured even if there are triggers.

#### 12.2.6 32-bit Compare Register

This is a 32-bit register for specifying a compare value. TMRC has ten built-in compare registers, TCCMP0 through TCCMP9. If values set in these compare registers match the value of the time base timer TBT, the match detection signal of a comparator becomes active. "Compare enable" or "compare disable" can be specified with the compare control register CMPCTL<CMPEN1:0>.

To set TCCMPn to a specific value, data must be transferred to TCCMPn in the order of lower to higher bits by using a byte data transfer instruction. If a byte data transfer instruction is used, data is transferred four times to TCCMPn.

Each compare register has a double-buffer structure, that is, TCCMPn forms a pair with a register buffer "n." "Enable" or "disable" of the double buffers is controlled by the compare control register CMPCTL <CMPRDEn>. If <CMPRDEn> is set to "0," the double buffers are disabled. If <CMPRDEn> is set to "1," they are enabled.

If the double buffers are enabled, data transfer from the register buffer "n" to the compare register TCCMPn takes place when the value of TBT matches that of TCCMPn.

Because TCCMPn is indeterminate when a reset is performed, it is necessary to prepare and write data in advance. A reset initializes CMPCTL <CMPRDEn> to "0" and disables the double buffers. To use the double buffers, data must be written to the compare register, <CMPRDEn> must be set to "1," and then the following data must be written to the register buffer.

TCCMPn and the register buffer are assigned to the same address. If <CMPRDEn> is "0," the same value is written to TCCMPn and each register buffer. If <CMPRDEn> is "1," data is written to each register buffer only. Therefore, to write an initial value to the compare register, it is necessary to set the double buffers to "disable."

#### 12.3 Register Description

	After reset	0	0	0	0	0	0	0	0
		TMRC	IDLE						
	Function	operation	0: Stop						
	Function	0: Disable	1: Run						
		1: Enable							

TMRC Control Register

- <I2TBT>: Controls the operation in IDLE mode
- <TCEN>: Specifies enabling/disabling of the TMRC operation. If set to "disable," a clock is not supplied to other registers of the TMRC module and, therefore, a reduction in power consumption is possible (a read of or a write to other registers cannot be executed). To use TMRC, the TMRC operation must be set to "enable" ("1") before making individual register settings of TMRC modules. If TMRC is operated and then set to "disable," individual register settings are retained.

#### (Note) Values read from bits 0 through 5 of TCCR are all "0."

				IDIKON	Register				
		7	6	5	4	3	2	1	0
TBTRUN	bit Symbol						TBTCAP	TBTPRUN	TBTRUN
(FFFFF401H)	Read/Write		F	2	_		R	/W	
	After reset	0	0	0	0	0	0	0	0
	Function					Ensure this is set to "0."	TBT counter software capture 0: Don't Care 1: Software capture	Timer Run/S 0: Stop & cl 1: Count	Stop Control ear

#### **TBTRUN** Register

- <TBTRUN>: Controls the TBT count operation
- <TBTPRUN>: Controls the TBT prescaler operation
- <TBTCAP>: If this is set to "1," the count value of the time base timer (TBT) is taken into the capture register TBTCAPn.

#### (Note) Values read from bits 4 through 7 of TBTRUN are all "0."

Fig. 12.3.1 TMRC-related Registers

			TI	3T Contro	l Register				
		7	6	5	4	3	2	1	0

	After reset	0	0	0	0	0	0	0	0
	Function	TBTIN Input noise removal 0: Disable 1: Enable	Ensure this	is set to "0."		TBT source cl 0000:	0001: фT 0100: фT 3 0111: ф ⁻	Г32 0101:	

<TBTCLK3:0>: This is an input clock for TBT. Clocks from "0000" to "0111" are available as prescaler output clocks. A clock "1111" is input through the TBTIN pin.

<TBTNF>: Controls the noise removal for the TBTIN pin input. If this is set to "0" (removal disabled), any input of more than 2/fsys (37ns@fperiph=fc=54MHz) is accepted as a source clock for TBT, at whichever level the TBTIN pin is, "H" or "L." If this is set to "1" (removal enabled), any input of less than 6/fsys (111ns@fperiph=fc=54MHz) is regarded as noise and removed, at whichever level the TBTIN pin is, "H" or "L." The range of removal changes depending on the selected clock gear and a system clock used.

TMPC Capture 2 Control Pegister

<CP2EG1:0>: Selects the effective edge of an input to the trigger input pin TC2IN of the capture 2 register (TCCAP2). If this is set to "00," the capture operation is disabled.

<TC2NF>: Controls the noise removal for the TC2IN pin input. If this is set to "0" (removal disabled), any input of more than 2/fsys (37ns@fperiph=fc=54MHz) is accepted as a trigger input for TCCAP2, at whichever level the TC2IN pin is, "H" or "L." If this is set to "1" (removal enabled), any input of less than 6/fsys (111ns@fperiph=fc=54MHz) is regarded as noise and removed, at whichever level the TC2IN pin is, "H" or "L." The range of removal changes depending on the selected clock gear and a system clock used.

#### (Note) Values read from bits 2 through 6 of CAP2CR are all "0."

----

<CP3EG1:0>: Selects the effective edge of an input to the trigger input pin TC3IN of the capture 3 register (TCCAP3). If this is set to "00," the capture operation is disabled.

<TC3NF>: Controls the noise removal for the TC3IN pin input. If this is set to "0" (removal disabled), any input of more than 2/fsys (37ns@fperiph=fc=54MHz) is accepted as a trigger input for TCCAP3, at whichever level the TC3IN pin is, "H" or "L." If this is set to "1" (removal enabled), any input of less than 6/fsys (111ns@fperiph=fc=54MHz)

is regarded as noise and removed, at whichever level the TC3IN pin is, "H" or "L." The range of removal changes depending on the selected clock gear and a system clock used.

#### 13. Serial Channel (SIO)

#### 13.1 Features

This device has seven serial I/O channels: SIO0 to SIO6. Each channel operates in either the UART mode (asynchronous communication) or the I/O interface mode (synchronous communication) which is selected by the user.

I/O interface mode — Mode 0: This is the mode to send and receive I/O data and associated synchronization signals (SCLK) to extend I/O.

Asynchronous (UART) mode: Mode 1: TX/RX Data Length: 7 bits Mode 2: TX/RX Data Length: 8 bits Mode 3: TX/RX Data Length: 9 bits

In the above modes 1 and 2, parity bits can be added. The mode 3 has a wakeup function in which the master controller can start up slave controllers via the serial link (multi-controller system). Figure shows the block diagram of SIO0.

Each channel consists of a prescaler, a serial clock generation circuit, a receive buffer and its control circuit, and a send buffer and its control circuit. Each channel functions independently.

As the SIOs 0 to 6 operate in the same way, Only SIO0 is described here.

Fig. 13.1 Data Format

TMP19A64(rev1.1)-13-1

Fig. 13.2.1 SIO0 Block Diagram

@fc = 54MHz

#### 13.3 Operation of Each Circuit (Channel 0)

#### 13.3.1 Prescaler

The device includes a 7-bit prescaler to generate necessary clocks to drive SIO0. The input clock  $\phi$ T0 to the prescaler is selected by SYSCR of CG <PRCK1:0> to provide the frequency of either fperiph/2, fperiph/4, fperiph/8, or fperiph/16. The clock frequency fperiph is either the clock "fgear," to be selected by SYSCR1<FPSEL> of CG, or the clock "fc" before it is divided by the clock gear.

The prescaler becomes active only when the baud rate generator is selected for generating the serial transfer clock. Table 13.3.1 lists the prescaler output clock resolution.

Clear peripheral	Clock gear value	Prescaler clock selection	Prescaler output clock resolution						
clock <fpsel></fpsel>	<gear2:0></gear2:0>	<prck1:0></prck1:0>	φT1	<b>φ</b> Τ4	φT16	φT64

Table 13.3.1 Clock Resolution to the Baud Rate Generator

(Note 1) The prescaler output clock φTn must be selected so that the relationship "φTn < fsys/2" is satisfied (so that φTn is slower than fsys/2).

#### (Note 2) Do not change the clock gear while SIO is operating.

#### (Note 3) The horizontal lines in the above table indicate that the setting is prohibited.

The serial interface baud rate generator uses four different clocks, i.e.,  $\phi T1$ ,  $\phi T4$ ,  $\phi T16$  and  $\phi T64$ , supplied from the prescaler output clock.

#### 13.3.2 Baud Rate Generator

The baud rate generator generates transmit and receive clocks to determine the serial channel transfer rate.

The baud rate generator uses either the  $\phi$ T1,  $\phi$ T4,  $\phi$ T16 or  $\phi$ T64 clock supplied from the 7-bit prescaler. This input clock selection is made by setting the baud rate setting register, BR0CR <BR0CK1:0>.

The baud rate generator contains built-in dividers for divide by 1, (N + m/16), and 16 where N is a number from 2 to 15 and m is a number from 0 to 15. The division is performed according to the settings of the baud rate control registers BR0CR <BR0ADDE> <BR0S3:0> and BR0ADD <BR0K3:0> to determine the resulting transfer rate.

- UART Mode:
  - 1) If BR0CR  $\langle$  BR0ADDE $\rangle = 0$ ,

The setting of BR0ADD  $\langle$ BR0K3:0 $\rangle$  is ignored and the counter is divided by N where N is the value set to BR0CR  $\langle$ BR0S3:0 $\rangle$ . (N = 1 to 16).

2) If BR0CR  $\langle$ BR0ADDE $\rangle = 1$ ,

The N + (16 - K)/16 division function is enabled and the division is made by using the values N (set in BR0CR <BR0S3:0>) and K (set in BR0ADD<BR0K3:0>). (N = 2 to 15, K = 1 to 15)

Note For the N values of 1 and 16, the above N+(16-K)/16 division function is inhibited. So, be sure to set BR0CR<BR0ADDE> to "0."

• <u>I/O interface mode:</u>

The N + (16 - K)/16 division function cannot be used in the I/O interface mode. Be sure to divide by N, by setting BR0CR <BR0ADDE> to "0."

- Baud rate calculation to use the baud rate generator:
  - 1) UART mode

Baud rate =  $\frac{\text{Baud rated generator input clock}}{\text{Frequency divided by the divide ratio}}$  /16

The highest baud rate out of the baud rate generator is 843.75 kbps when  $\phi$ T1 is 13.5 MHz.

The fsys/2 frequency, obtained by dividing the system clock by 2, can be used as the serial clock. In this case, the highest baud rate will be 1.68 Mbps when fsys is 54 MHz.

2) I/O interface mode

Baud rate =  $\frac{\text{Baud rated generator input clock}}{\text{Frequency divided by the divide ratio}}$  /2

The highest baud rate will be generated when  $\phi$ T1 is 13.5 MHz. If double buffering is used, the divide ratio can be set to "1" and the resulting output baud rate will be 6.75 Mbps. (If double buffering is not used, the highest baud rate will be 3.375 Mbps applying the divide ratio of "2.")

- Example baud rate setting:
  - 1) Division by an integer (divide by N):

Selecting fc = 54 MHz for fperiph, setting  $\phi$ T0 to fperiph/16, using the baud rate generator input clock  $\phi$ T1, setting the divide ratio N (BR0CR<BR0S3:0>) = 4, and setting BR0CR<BR0ADDE> = "0," the resulting baud rate in the UART mode is calculated as follows:

* Clocking conditions System clock : High-speed (fc) High speed clock gear : x 1 (fc) Prescaler clock : fperiph/16 (fperiph = fsys) Baud rate =  $\frac{fc/32}{4}$  /16 = 54 × 10⁶ / 32 / 4 / 16 = 26367 (bps)

### (Note) The divide by (N + (16-K)/16) function is inhibited and thus BR0ADD <BR0K3:0> is ignored.

2) For divide by N + (16-K)/16 (only for UART mode):

Selecting fc = 54 MHz MHz for fperiph, setting  $\phi$ T0 to fperiph/16, using the baud rate generator input clock  $\phi$ T2, setting the divide ratio N (BR0CR<BR0S3:0>) = 4, setting K (BR0ADD<BR0K3:0>) = 14, and selecting BR0CR<BR0ADDE> = 1, the resulting baud rate is calculated as follows:

* Clocking conditions  
System clock : High-speed (fc)  
High-speed clock gear : x 1 (fc)  
Prescaler clock : fperiph/16 (fperiph = fsys)  
Baud rate = 
$$\frac{fc/32}{4 + \frac{(16 - 14)}{16}}/16$$
  
=  $54 \times 10^6 / 32 / (4 + \frac{2}{16}) / 16 = 25568$  (bps)

Also, an external clock input may be used as the serial clock. The resulting baud rate calculation is shown below:

- Baud rate calculation for an external clock input:
  - 1) UART mode

Baud Rate = external clock input / 16

In this, the period of the external clock input must be equal to or greater than 4/fsys.

If fsys = 54 MHz, the highest baud rate will be 54 / 4 / 16 = 844 (kbps).

2) I/O interface mode

Baud Rate = external clock input

When double buffering is used, it is necessary to satisfy the following relationship:

External clock input period > 12/fsys

Therefore, when fsys = 54 MHz, the baud rate must be set to a rate lower than 54 / 12 = 4.5 (Mbps).

When double buffering is not used, it is necessary to satisfy the following relationship:

External clock input period > 16/fsys

Therefore, when fsys = 54 MHz, the baud rate must be set to a rate lower than 54 / 16 = 3.375 (Mbps).

Example baud rates for the UART mode are shown in Table 13.3.2.1 and Table 13.3.2.2.

Unit (khns)

fc [MHz]	Input clock Divide ratio N (Set to BR0CR <br0s3:0>)</br0s3:0>	φT1 (fc/4)	φT4 (fc/16)	φT16 (fc/64)	φT64 (fc/256)

Table 13.3.2.1 Selection of UART Baud Rate (Use the baud rate generator with BR0CR  $\langle BR0ADDE \rangle = 0$ )

### (Note) This table shows the case where the system clock is set to fc, the clock gear is set to fc/1, and the prescaler clock is set to fperiph/2.

#### Table 13.3.2.2 Selection of UART Baud Rate

(The TMRB4 timer output (internal TB4OUT) is used with the timer input clock set to  $\phi$ T0.)

						Unit (kbps)
fc TB4RG0H/L	29.4912 MHz	24.576 MHz	24 MHz	19.6608 MHz	16 MHz	12.288 MHz
0001H	230.4	192	187.5	153.6	125	96
0002H	115.2	96	93.75	76.8	62.5	48
0003H	76.8	64	62.5	51.2	41.67	32
0004H	57.6	48	46.88	38.4	31.25	24
0005H	46.08	38.4	37.5	30.72	25	19.2
0006H	38.4	32	31.25	25.6	20.83	16
0008H	28.8	24	23.44	19.2	15.63	12
000AH	23.04	19.2	18.75	15.36	12.5	9.6
0010H	14.4	12	11.72	9.6	7.81	6
0014H	11.52	9.6	9.38	7.68	6.25	4.8

Baud rate calculation to use the TMRB4 timer:

Transfer rate =  $\frac{\text{Clock frequency selected by SYSCR0 < PRCK1: 0 > }}{\text{Clock frequency selected by SYSCR0 < PRCK1: 0 > }}$ 

TB4REG 
$$\times \underline{2} \times 16$$

(When input clock to the timer TMRB4 is  $\phi$ T0)

- (Note 1) In the I/O interface mode, the TMRB4 timer output signal cannot be used internally as the transfer clock.
- (Note 2) This table shows the case where the system clock is set to fc, the clock gear is set to fc/1, and the prescaler clock is set to fperiph/4.

#### 13.3.3 Serial Clock Generation Circuit

This circuit generates basic transmit and receive clocks.

• <u>I/O interface mode:</u>

In the SCLK output mode with the SC0CR <IOC> serial control register set to "0," the output of the previously mentioned baud rate generator is divided by 2 to generate the basic clock.

In the SCLK input mode with SCOCR <IOC> set to "1," rising and falling edges are detected according to the SCOCR <SCLKS> setting to generate the basic clock.

• Asynchronous (UART) mode:

According to the settings of the serial control mode register SC0MOD0  $\langle$ SC1:0 $\rangle$ , either the clock from the baud rate register, the system clock ( $f_{SYS}/2$ ), the internal output signal of the TMRB4 timer, or the external clock (SCLKO pin) is selected to generate the basic clock, SIOCLK.

#### 13.3.4 Receive Counter

The receive counter is a 4-bit binary counter used in the asynchronous (UART) mode and is up-counted by SIOCLK. Sixteen SIOCLK clock pulses are used in receiving a single data bit while the data symbol is sampled at the seventh, eighth, and ninth pulses. From these three samples, majority logic is applied to decide the received data.

#### 13.3.4 Receive Control Unit

• <u>I/O interface mode:</u>

In the SCLK output mode with SC0CR <IOC> set to "0," the RXD0 pin is sampled on the rising edge of the shift clock output to the SCLK0 pin.

In the SCLK input mode with SCOCR <IOC> set to "1," the serial receive data RXD0 pin is sampled on the rising or falling edge of SCLK input depending on the SCOCR <SCLKS> setting.

• Asynchronous (UART) mode:

The receive control unit has a start bit detection circuit, which is used to initiate receive operation when a normal start bit is detected.

#### 13.3.5 Receive Buffer

The receive buffer is of a dual structure to prevent overrun errors. The first receive buffer (a shift register) stores the received data bit-by-bit. When a complete set of bits have been stored, they are moved to the second receive buffer (SC0BUF). At the same time, the receive buffer full flag (SC0MOD2 "RBFLL") is set to "1" to indicate that valid data is stored in the second receive buffer. However, if the receive FIFO is set enabled, the receive data is moved to the receive FIFO and this flag is immediately cleared.

If the receive FIFO has been disabled (SCOFCNF  $\langle \text{CNFG} \rangle = 0$  and SC0MOD1 $\langle \text{FDPX1:0} \rangle = 01$ ), the INTRX0 interrupt is generated at the same time. If the receive FIFO has been enabled (SCNFCNF  $\langle \text{CNFG} \rangle = 1$  and SC0MOD1 $\langle \text{FDPX1:0} \rangle = 01/11$ ), an interrupt will be generated according to the SC0RFC  $\langle \text{RIL2:0} \rangle$  setting.

The CPU will read the data from either the second receive buffer (SC0BUF) or from the receive FIFO (the address is the same as that of the receive buffer). If the receive FIFO has not been enabled, the receive buffer full flag SC0MOD2<RBFLL> is cleared to "0" by the read operation. The next data received can be stored in the first receive buffer even if the CPU has not read the previous data from the second receive

buffer (SC0BUF) or the receive FIFO.

If SCLK is set to generate clock output in the I/O interface mode, the double buffer control bit SC0MOD2 <WBUF> can be programmed to enable or disable the operation of the second receive buffer (SCOBUF).

By disabling the second receive buffer (i.e., the double buffer function) and also disabling the receive FIFO (SCOFCNF  $\langle \text{CNFG} \rangle = 0$  and  $\langle \text{FDPX1:0} \rangle = 01$ ), handshaking with the other side of communication can be enabled and the SCLK output stops each time one frame of data is transferred. In this setting, the CPU reads data from the first receive buffer. By the read operation of CPU, the SCLK output resumes.

If the second receive buffer (i.e., double buffering) is enabled but the receive FIFO is not enabled, the SCLK output is stopped when the first receive data is moved from the first receive buffer to the second receive buffer and the next data is stored in the first buffer filling both buffers with valid data. When the second receive buffer is read, the data of the first receive buffer is moved to the second receive buffer and the SCLK output is resumed upon generation of the receive interrupt INTRX. Therefore, no buffer overrun error will be caused in the I/O interface SCLK output mode regardless of the setting of the double buffer control bit SC0MOD2 <WBUF>.

If the second receive buffer (double buffering) is enabled and the receive FIFO is also enabled (SCNFCNF  $\langle$ CNFG $\rangle = 1$  and  $\langle$ FDPX1:0 $\rangle = 01/11$ ), the SCLK output will be stopped when the receive FIFO is full (according to the setting of SCOFNCF  $\langle$ RFST $\rangle$ ) and both the first and second receive buffers contain valid data. Also in this case, if SCOFCNF  $\langle$ RXTXCNT $\rangle$  has been set to "1," the receive control bit RXE will be automatically cleared upon suspension of the SCLK output. If it is set to "0," automatic clearing will not be performed.

# (Note) In this mode, the SC0CR <OEER> flag is insignificant and the operation is undefined. Therefore, before switching from the SCLK output mode to another mode, the SC0CR register must be read to initialize this flag.

In other operating modes, the operation of the second receive buffer is always valid, thus improving the performance of continuous data transfer. If the receive FIFO is not enabled, an overrun error occurs when the data in the second receive buffer (SC0BUF) has not been read before the first receive buffer is full with the next receive data. If an overrun error occurs, data in the first receive buffer will be lost while data in the second receive buffer and the contents of SC0CR <RB8> remain intact. If the receive FIFO is enabled, the FIFO must be read before the FIFO is full and the second receive buffer is written by the next data through the first buffer. Otherwise, an overrun error will be generated and the receive FIFO overrun error flag will be set. Even in this case, the data already in the receive FIFO remains intact.

The parity bit to be added in the 8-bit UART mode as well as the most significant bit in the 9-bit UART mode will be stored in SCOCR <RB8>.

In the 9-bit UART mode, the slave controller can be operated in the wake-up mode by setting the wake-up function SC0MOD0 <WU> to "1." In this case, the interrupt INTRX0 will be generated only when SC0CR <RB8> is set to "1."

#### 13.3.6 Receive FIFO Buffer

In addition to the double buffer function already described, data may be stored using the receive FIFO buffer. By setting <CNFG> of the SC0FCNF register and <FDPX1:0> of the SC0MOD1 register, the 4-byte receive buffer can be enabled. Also, in the UART mode or I/O interface mode, data may be stored up to a predefined fill level. When the receive FIFO buffer is to be used, be sure to enable the double buffer function.

If data with parity bit is to be received in the UART mode, parity check must be performed each time a data frame is received.

#### 13.3.7 Receive FIFO Operation

① I/O interface mode with SCLK output:

The following example describes the case a 4-byte data stream is received in the half duplex mode:

SCORFC<7:6>=01: Clears receive FIFO and sets the condition of interrupt generation.

SC0RFC<1:0>=00: Sets the interrupt to be generated at fill level 4.

SC0FCNF <1:0>=10111: Automatically inhibits continued reception after reaching the fill level. The number of bytes to be used in the receive FIFO is the same as the interrupt generation fill level.

In this condition, 4-byte data reception may be initiated by setting the half duplex transmission mode and writing "1" to the RXE bit. After receiving 4 bytes, the RXE bit is automatically cleared and the receive operation is stopped (SCLK is stopped).

Fig. 13.3.7.1 Receive FIFO Operation

② I/O interface mode with SCLK input:

The following example describes the case a 10-byte data stream is received:

SCORFC < 7:6 > = 10: Clears receive FIFO and sets the condition of interrupt generation

SCORFC <1:0> = 00: Sets the interrupt to be generated at fill level 4.

SC0FCNF < 1:0 > = 10101: Automatically allows continued reception after reaching the fill level.

The number of bytes to be used in the receive FIFO is the maximum allowable number.

In this condition, 4-byte data reception can be initiated along with the input clock by setting the half duplex transmission mode and writing "1" to the RXE bit. When the 4-byte data reception is completed, the receive FIFO interrupt will be generated.

Note that preparation for the next data reception can be managed in this setting, i.e., the next 4-byte data can be received before data is fully read from the FIFO.

Fig. 13.3.7.2 Receive FIFO Operation

#### 13.3.8 Transmit Counter

The transmit counter is a 4-bit binary counter used in the asynchronous communication (UART) mode. It is counted by SIOCLK as in the case of the receive counter and generates a transmit clock (TXDCLK) on every 16th clock pulse.

Fig. 13.3.8.1 Transmit Clock Generation

# 13.3.9 Transmit Control Unit

<u>I/O interface mode:</u>

In the SCLK output mode with SCOCR <IOC> set to "0," each bit of data in the send buffer is output to the TXD0 pin on the rising edge of the shift clock output from the SCLK0 pin.

In the SCLK input mode with SCOCR <IOC> set to "1," each bit of data in the send buffer is output to the TXD0 pin on the rising or falling edge of the input SCLK signal according to the SCOCR <SCLKS> setting.

• Asynchronous (UART) mode:

When the CPU writes data to the send buffer, data transmission is initiated on the rising edge of the next TXDCLK and the transmit shift clock (TXDSFT) is also generated.

#### <u>Handshake function</u>

The CTS pin enables frame by frame data transmission so that overrun errors can be prevented. This function can be enabled or disabled by SC0MOD0 <CTSE>.

When the CTS pin is set to the "H" level, the current data transmission can be completed but the next data transmission is suspended until the  $\overline{\text{CTS}}$  pin returns to the "L" level. However in this case, the INTTX0 interrupt is generated, the next transmit data is requested to the CPU, data is written to the send buffer, and it waits until it is ready to transmit data.

Although no RTS pin is provided, a handshake control function can be easily implemented by assigning a port for the  $\overline{\text{RTS}}$  function. By setting the port to "H" level upon completion of data reception (in the receive interrupt routine), the transmit side can be requested to suspend data transmission.

Fig. 13.3.9.1 Handshake Function

(Note) If the CTS signal is set to "H" during transmission, the next data transmission is suspended after the current transmission is completed.
 Data transmission starts on the first falling edge of the TXDCLK clock after CTS is set to "L."

Fig. 13.3.9.2 CTS (Clear to Send) Signal Timing

#### 13.3.10 Transmit Buffer

The send buffer (SC0BUF) is in a dual structure. The double buffering function may be enabled or disabled by setting the double buffer control bit <WBUF> in serial mode control register 2 (SC0MOD2). If double buffering is enabled, data written to send buffer 2 (SC0BUF) is moved to send buffer 1 (shift register).

If the transmit FIFO has been disabled (SCOFCNF  $\langle \text{CNFG} \rangle = 0$  or 1 and  $\langle \text{FDPX1:0} \rangle = 01$ ), the INTTX interrupt is generated at the same time and the send buffer empty flag  $\langle \text{TBEMP} \rangle$  of SCOMOD2 is set to "1." This flag indicates that send buffer 2 is now empty and that the next transmit data can be written. When the next data is written to send buffer 2, the  $\langle \text{TBEMP} \rangle$  flag is cleared to "0."

If the transmit FIFO has been enabled (SCNFCNF  $\langle$ CNFG $\rangle = 1$  and  $\langle$ FDPX1:0 $\rangle = 10/11$ ), any data in the transmit FIFO is moved to the send buffer 2 and  $\langle$ TBEMP $\rangle$  flag is immediately cleared to "0." The CPU writes data to send buffer 2 or to the transmit FIFO.

If the transmit FIFO is disabled in the I/O interface SCLK input mode and if no data is set in send buffer 2 before the next frame clock input, which occurs upon completion of data transmission from send buffer 1, an under-run error occurs and a serial control register (SCOCR) <PERR> parity/under-run flag is set.

If the transmit FIFO is enabled in the I/O interface SCLK input mode, when data transmission from send buffer 1 is completed, the send buffer 2 data is moved to send buffer 1 and any data in transmit FIFO is moved to send buffer 2 at the same time.

If the transmit FIFO is disabled in the I/O interface SCLK output mode, when data in send buffer 2 is moved to send buffer 1 and the data transmission is completed, the SCLK output stops. So, no under-run errors can be generated.

If the transmit FIFO is enabled in the I/O interface SCLK output mode, the SCLK output stops upon completion of data transmission from send buffer 1 if there is no valid data in the transmit FIFO.

# Note) In the I/O interface SCLK output mode, the SC0CR <PEER> flag is insignificant. In this case, the operation is undefined. Therefore, to switch from the SCLK output mode to another mode, SC0CR must be read in advance to initialize the flag.

If double buffering is disabled, the CPU writes data only to send buffer 1 and the transmit interrupt INTTX is generated upon completion of data transmission.

If handshaking with the other side is necessary, set the double buffer control bit <WBUF> to "0" (disable) to disable send buffer 2; any setting for the transmit FIFO should not be performed.

# 13.3.11 Transmit FIFO Buffer

In addition to the double buffer function already described, data may be stored using the transmit FIFO buffer. By setting <CNFG> of the SC0FCNF register and <FDPX1:0> of the SC0MOD1 register, the 4-byte send buffer can be enabled. In the UART mode or I/O interface mode, up to 4 bytes of data may be stored.

If data is to be transmitted with a parity bit in the UART mode, parity check must be performed on the receive side each time a data frame is received.

#### 13.3.12 Transmit FIFO Operation

① I/O interface mode with SCLK output (normal mode):

The following example describes the case a 4-byte data stream is transmitted:

SC0TFC < 7:6 > = 01: Clears transmit FIFO and sets the condition of interrupt generation

SC0TFC <1:0> = 00: Sets the interrupt to be generated at fill level 0.

SCOFCNF < 1:0 > = 01011: Inhibits continued transmission after reaching the fill level.

In this condition, data transmission can be initiated by setting the transfer mode to half duplex, writing 4 bytes of data to the transmit FIFO, and setting the <TXE> bit to "1." When the last transmit data is moved to the send buffer, the transmit FIFO interrupt is generated. When transmission of the last data is completed, the clock is stopped and the transmission sequence is terminated.

Fig. 13.3.12.1 Transmit FIFO Operation

② I/O interface mode with SCLK input (normal mode):

The following example describes the case a 4-byte data stream is transmitted:

SC0TFC <1:0> = 01: Clears the transmit FIFO and sets the condition of interrupt generation.

SC0TFC <7:2> = 000000: Sets the interrupt to be generated at fill level 0.

SC0FCNF <4:0> = 01001: Allows continued transmission after reaching the fill level.

In this condition, data transmission can be initiated along with the input clock by setting the transfer mode to half duplex, writing 4 bytes of data to the transmit FIFO, and setting the  $\langle TXE \rangle$  bit to "1." When the last transmit data is moved to the send buffer, the transmit FIFO interrupt is generated

Fig. 13.3.12.2 Transmit FIFO Operation

#### 13.3.13 Parity Control Circuit

If the parity addition bit <PE> of the serial control register SC0CR is set to "1," data is sent with the parity bit. Note that the parity bit may be used only in the 7- or 8-bit UART mode. The <EVEN> bit of SC0CR selects either even or odd parity.

Upon data transmission, the parity control circuit automatically generates the parity with the data written to the send buffer (SC0BUF). After data transmission is complete, the parity bit will be stored in SC0BUF bit 7 <TB7> in the 7-bit UART mode and in bit 7 <TB8> in the serial mode control register SC0MOD in the 8-bit UART mode. The <PE> and <EVEN> settings must be completed before data is written to the send buffer.

Upon data reception, the parity bit for the received data is automatically generated while the data is shifted to receive buffer 1 and moved to receive buffer 2 (SC0BUF). In the 7-bit UART mode, the parity generated is compared with the parity stored in SC0BUF <RB7>, while in the 8-bit UART mode, it is compared with the bit 7 <RB8> of the SC0CR register. If there is any difference, a parity error occurs and the <PERR> flag of the SC0CR register is set.

In the I/O interface mode, the SCOCR <PERR> flag functions as an under-run error flag, not as a parity flag.

#### 13.3.14 Error Flag

Three error flags are provided to increase the reliability of received data.

1. Overrun error <OERR>: Bit 4 of the serial control register SCOCR

In both UART and I/O interface modes, this bit is set to "1" when an error is generated by completing the reception of the next frame receive data before the receive buffer has been read. If the receive FIFO is enabled, the received data is automatically moved to the receive FIFO and no overrun error will be generated until the receive FIFO is full (or until the usable bytes are fully occupied). This flag is set to "0" when it is read. In the I/O interface SCLK output mode, no overrun error is generated and therefore, this flag is inoperative and the operation is undefined.

2. Parity error/under-run error <PERR>: Bit 3 of the SCOCR register

In the UART mode, this bit is set to "1" when a parity error is generated. A parity error is generated when the parity generated from the received data is different from the parity received. This flag is set to "0" when it is read.

In the I/O interface mode, this bit indicates an under-run error. When the double buffer control bit <WBUF> of the serial mode control register SC0MOD2 is set to "1" in the SCLK input mode, if no data is set to the transmit double buffer before the next data transfer clock after completing the transmission from the transmit shift register, this error flag is set to "1" indicating an under-run error. If the transmit FIFO is enabled, any data content in the transmit FIFO will be moved to the buffer. When the transmit FIFO and the double buffer are both empty, an under-run error will be generated. Because no under-run errors can be generated in the SCLK output mode, this flag is inoperative and the operation is undefined. If send buffer 2 is disabled, the under-run flag <PERR> will not be set. This flag is set to "0" when it is read.

3. Framing error <FERR>: Bit 2 of the SCOCR register

In the UART mode, this bit is set to "1" when a framing error is generated. This flag is set to "0" when it is read. A framing error is generated if the corresponding stop bit is determined to be "0" by sampling the bit at around the center. Regardless of the *<*SBLEN> (stop bit length) setting of the serial mode control register 2, SCOMOD2, the stop bit status is determined by only 1 bit on the receive side.

Operation mode	Error flag	Function
UART	OERR	Overrun error flag
	PERR	Parity error flag
	FERR	Framing error flag
I/O interface	OERR	Overrun error flag
(SCLK input)	PERR	Underrun error flag (WBUF = 1)
		Fixed to 0 (WBUF = 0)
	FERR	Fixed to 0
I/O interface	OERR	Operation undefined
(SCLK output)	PERR	Operation undefined
	FERR	Fixed to 0

#### 13.3.15 Direction of Data Transfer

In the I/O interface mode, the direction of data transfer can be switched between "MSB first" and "LSB first" by the data transfer direction setting bit <DRCHG> of the SC0MOD2 serial mode control register 2. Don't switch the direction when data is being transferred.

#### 13.3.16 Stop Bit Length

In the UART mode transmission, the stop bit length can be set to either 1 or 2 bits by bit 4 <SBLEN> of the SC0MOD2 register.

#### 13.3.17 Status Flag

If the double buffer function is enabled (SC0MOD2  $\langle WBUF \rangle = "1"$ ), the bit 6 flag  $\langle RBFLL \rangle$  of the SC0MOD2 register indicates the condition of receive buffer full. When one frame of data has been received and transferred from buffer 1 to buffer 2, this bit is set to "1" to show that buffer 2 is full (data is stored in buffer 2). When the receive buffer is read by CPU/DMAC, it is cleared to "0." If  $\langle WBUF \rangle$  is set to "0," this bit is insignificant and must not be used as a status flag.

When double buffering is enabled (SC0MOD2  $\langle WBUF \rangle = "1"$ ), the bit 7 flag  $\langle TBEMP \rangle$  of the SC0MOD2 register indicates that send buffer 2 is empty. When data is moved from send buffer 2 to send buffer 1 (shift register), this bit is set to "1" indicating that send buffer 2 is now empty. When data is set to the send buffer by CPU/DMAC, the bit is cleared to "0." If  $\langle WBUF \rangle$  is set to "0," this bit is insignificant and must not be used as a status flag.

#### 13.3.18 Configurations of Send/Receive Buffers

		<wbuf> = 0</wbuf>	<wbuf> = 1</wbuf>
UART	Transmit buffer	Single	Double
UARI	Receive buffer	Double	Double
I/O interface	Transmit buffer	Single	Double
(SCLK input)	Receive buffer	Double	Double
I/O interface	Transmit buffer	Single	Double
(SCLK output)	Receive buffer	Single	Double

## 13.3.19 Signal Generation Timing

#### ① UART Mode:

Receive Side

Mode	9-bit	8-bit with parity	8-bit, 7-bit, and 7-bit with parity
Interrupt generation timing	Around the center of the 1st stop bit	Around the center of the 1st stop bit	Around the center of the 1st stop bit
Framing error timing	Around the center of the stop bit	Around the center of the stop bit	Around the center of the stop bit
Parity error generation timing	_	Around the center of the last (parity) bit	Around the center of the last (parity) bit
Overrun error generation timing	Around the center of the stop bit	Around the center of the stop bit	Around the center of the stop bit

#### Transmit Side

Mode	9-bit	8-bit with parity	8-bit, 7-bit, and 7-bit with parity
Interrupt generation timing ( <wbuf> = 0)</wbuf>	Just before the stop bit is sent	Just before the stop bit is sent	Just before the stop bit is sent
Interrupt generation timing ( <wbuf> = 1)</wbuf>		Immediately after data is moved to send buffer 1 (just before start bit transmission)	Immediately after data is moved to send buffer 1 (just before start bit transmission)

#### ② I/O interface mode:

Receive Side

Interrupt generation timing	SCLK output mode	Immediately after the rising edge of the last SCLK
(WBUF = 0)	SCLK input mode	Immediately after the rising or falling edge of the last SCLK (for rising or falling edge mode, respectively)
Interrupt generation timing	SCLK output mode	Immediately after the rising edge of the last SCLK (just after data transfer to receive buffer 2) or just after receive buffer 2 is read
(WBUF = 1)		Immediately after the rising edge or falling edge of the last SCLK depending on the rising or falling edge triggering mode, respectively (right after data is moved to receive buffer 2)
Overrun error generation timing	SCLK input mode	Immediately after the rising or falling edge of the last SCLK (for rising or falling edge mode, respectively)

#### Transmit Side

Interrupt generation timing	SCLK output mode	Immediately after the rising edge of the last SCLK
(WBUF = 0)	-	Immediately after the rising or falling edge of the last SCLK (for rising or falling edge mode, respectively)
Interrupt generation timing		Immediately after the rising edge of the last SCLK or just after data is moved to send buffer 1
(WBUF = 1)		Immediately after the rising or falling edge of the last SCLK (for the rising or falling edge mode, respectively) or just after data is moved to send buffer 1
Under-run error generation timing		Immediately after the falling or rising edge of the next SCLK (for the rising or falling edge triggering mode, respectively)

Note 1) Do not modify any control register when data is being sent or received (in a state ready to send or receive).

- Note 2) Do not stop the receive operation (by setting SC0MOD0 <RXE> = "0") when data is being received.
- Note 3) Do not stop the transmit operation (by setting SC0MOD1 <TXE> = "0") when data is being transmitted.

# 13.4 Register Description (Only for Channel 0)

#### Note) With <RXE> set to "0," set each mode register (SC0MOD0, SC0MOD1 and SC0MOD2). Then set <RXE> to "1."

0
Write "0."

Fig. 12.4.2 Carial Made Control Deviates	
Fig. 13.4.2 Serial Mode Control Register	
ing. To: T.E Contai Modo Control Togloto	

- Specifies the interval time of continuous transmission when double buffering or FIFO is enabled <SINT2:0>: in the I/O interface mode. This parameter is invalid for the UART mode or when an external clock is used.
- <TXE>: This bit enables transmission and is valid for all the transfer modes. If disabled while transmission is in progress, transmission is inhibited only after the current frame of data is completed for transmission.
- Configures the transfer mode in the I/O interface mode. Also configures the FIFO if it is enabled. <FDPX1:0>: In the UART mode, it is used only to specify the FIFO configuration.
- <I2S0>: Specifies the Idle mode operation.

SC0MOD2 (0xFFFF_F266)

	7	6	5	4	3	2	1	0
bit Symbol	TBEMP	RBFLL	TXRUN	SBLEN	DRCHG	WBUF	SWRST1	SWRST0
Read/Write		R/W						
After reset	1	0	0	0	0	0	0	0
Function	Send buffer empty flag 0: full 1: Empty	Receive buffer full flag 0: Empty 1: full	In transmissi on flag 0: Stop 1: Start	Stop bit 0: 1-bit 1: 2-bit	Setting transfer direction 0: LSB first 1: MSB first	W-buffer 0: Disable 1: Enable	Soft reset Overwrite "( to reset	)1" on "10"

- <SWRST1:0>: Overwriting "01" in place of "10" generates a software reset. When this software reset is executed, the mode register parameters SC0MOD0 <RXE>, SC0MOD1<TXE>, SC0MOD2 <TBEMP>, <RBFLL>, and <TXRUN>, control register parameters SC0CR <OERR>, <PERR>, and <FERR>, and their internal circuits are initialized.
- <WBUF>: This parameter enables or disables the send/receive buffers to send (in both SCLK output/input modes) and receive (in SCLK output mode) data in the I/O interface mode and to transmit data in the UART. In all other modes, double buffering is enabled regardless of the <WBUF> setting.
- <DRCHG>: Specifies the direction of data transfer in the I/O interface mode. In the UART mode, it is fixed to LSB first.

<TXRUN>: This is a status flag to show that data transmission is in progress.

When this bit is set to "1," it indicates that data transmission operation is in progress. If it is "0," the bit 7 <TBEMP> is set to "1" to indicate that the transmission has been fully completed and the same <TBEMP> is set to "0" to indicate that the send buffer contains some data waiting for the next transmission.

- <RBFLL>: This is a flag to show that the receive double buffers are full. When a receive operation is completed and received data is moved from the receive shift register to the receive double buffers, this bit changes to "1" while reading this bit changes it to "0." If double buffering is disabled, this flag is insignificant.
- <TBEMP>: This flag shows that the send double buffers are empty. When data in the send double buffers is moved to the send shift register and the double buffers are empty, this bit is set to "1." Writing data again to the double buffers sets this bit to "0."

If double buffering is disabled, this flag is insignificant.

<SBLEN>: This specifies the length of stop bit transmission in the UART mode. On the receive side, the decision is made using only a single bit regardless of the <SBLEN> setting.

# (Note) While data transmission is in progress, any software reset operation must be executed twice in succession.

Fig. 13.4.3 Serial Mode Control Register

# (Note) Any error flag is cleared when read.

Fig. 13.4.4 Serial Control Register (for SIO0, SC0CR)

(Note 3) The "N + (16 - K)/16" division function can only be used in the UART mode. In the I/O interface mode, the "N + (16 - K)/16" division function must be disabled (prohibited) by setting BR0CR <BR0ADDE> to "0."

Fig. 13.4.5 Baud Rate Generator Control (for SIO0, BR0CR, BR0ADD)

SC0BUF (0xFFFF_F260)

Fig. 13.4.6 SIO0 Send/Receive Buffer Register

<CNFG>: If enabled, the SCOMOD1 <FDPX1:0> setting automatically configures FIFO as follows:

<FDPX1:0> = 01 (Half duplex RX) ---- 4-byte RX FIFO

<FDPX1:0> = 10 (Half duplex TX) ---- 4-byte TX FIFO

<FDPX1:0> = 11 (Full duplex) ------ 2-Byte RX FIFO + 2-Byte TX FIFO

<RXTXCNT>:0 The function to automatically disable RXE/TXE bits is disabled.

1: If enabled, the SCOMOD1 <FDPX1:0> is used to set as follows:

<fdpx1:0> = 01 (Half duplex RX)</fdpx1:0>	When the RX FIFO is filled up to the specified number of valid bytes, RXE is automatically set to "0" to inhibit further reception.
<fdpx1:0> = 10 (Half duplex TX)</fdpx1:0>	When the TX FIFO is empty, TXE is automatically set to "0" to inhibit further transmission.
<fdpx1:0> = 11 (Full duplex)</fdpx1:0>	When either of the above two conditions is satisfied, TXE/RXE are automatically set to "0" to inhibit further transmission and reception.

<RFIE>: When RX FIFO is enabled, receive interrupts are enabled or disabled by this parameter.

<TFIE>: When TX FIFO is enabled, transmit interrupts are enabled or disabled by this parameter.

<RFST>: When RX FIFO is enabled, the number of RX FIFO bytes to be used is selected.

0: The maximum number of bytes of the FIFO configured 4 bytes when <FDPX1:0> = 01 (Half duplex RX) and 2 bytes for <FDPX1:0> = 11 (Full duplex)

1:Same as the fill level for receive interrupt generation specified by SCORFC <RIL5:0>.

#### (Note 1) Regarding TX FIFO, the maximum number of bytes being configured is always available. The available number of bytes is the bytes already written to the TX FIFO.

	Read/Write				R				R/W
	After reset	0	0	0	0	0	0	0	0
(0xFFFF_F267)	Function								SIO operation 0: Disable 1: Enable

<SIOE>: It specifies SIO operation. When SIO operation is disabled, the clock will not be supplied to the SIO module except for the register part and thus power dissipation can be reduced (other registers cannot be accessed for read/write operation). When SIO is to be used, be sure to enable SIO by setting "1" to this register before setting any other registers of the SIO module. If SIO is enabled once and then disabled, any register setting is maintained.

Fig. 13.4.12 SIO Enable Register

# 13.5 Operation in Each Mode

#### 13.5.1 Mode 0 (I/O Interface Mode)

Mode 0 consists of two modes, i.e., the "SCLK output" mode to output synchronous clock and the "SCLK input" mode to accept synchronous clock from an external source. The following operational descriptions are for the case use of FIFO is disabled. For details of FIFO operation, refer to the previous sections describing receive/transmit FIFO functions.

#### ① Sending data

#### SCLK output mode

In the SCLK output mode, if SC0MOD2<WBUF> is set to "0" and the send double buffers are disabled, 8 bits of data are output from the TXD0 pin and the synchronous clock is output from the SCLK0 pin each time the CPU writes data to the send buffer. When all data is output, the INTTX0 interrupt is generated.

If SCOMOD2 <WBUF> is set to "1" and the send double buffers are enabled, data is moved from send buffer 2 to send buffer 1 when the CPU writes data to send buffer 2 while data transmission is halted or when data transmission from send buffer 1 (shift register) is completed. When data is moved from send buffer 2 to send buffer 1, the send buffer empty flag SCOMOD2 <TBEMP> is set to "1," and the INTTX0 interrupt is generated. If send buffer 2 has no data to be moved to send buffer 1, the INTTX0 interrupt is not generated and the SCLK0 output stops.

<WBUF> = "1" (if double buffering is enabled) (if there is data in buffer 2)

<WBUF> = "1" (if double buffering is enabled) (if there is no data in buffer 2)

Fig. 13.5.1.11 Send Operation in the I/O Interface Mode (SCLK0 Output Mode)

#### SCLK input mode

In the SCLK input mode, if SC0MOD2 <WBUF> is set to "0" and the send double buffers are disabled, 8-bit data that has been written in the send buffer is output from the TXD0 pin when the SCLK0 input becomes active. When all 8 bits are sent, the INTTX0 interrupt is generated. The next send data must be written before the timing point "A" as shown in Fig. 13.5.1.2.

If SCOMOD2 <WBUF> is set to "1" and the send double buffers are enabled, data is moved from send buffer 2 to send buffer 1 when the CPU writes data to send buffer 2 before the SCLK0 becomes active or when data transmission from send buffer 1 (shift register) is completed. As data is moved from send buffer 2 to send buffer 1, the send buffer empty flag SC0MOD2 <TBEMP> is set to "1" and the INTTX0 interrupt is generated. If the SCLK0 input becomes active while no data is in send buffer 2, although the internal bit counter is started, an under-run error occurs and 8-bit dummy data (FFh) is sent.

<WBUF> = "0" (if double buffering is disabled)

<WBUF> = "1" (if double buffering is enabled) (if there is data in buffer 2)

<WBUF> = "1" (if double buffering is enabled) (if there is no data in buffer 2)

Fig. 13.5.1.2 Send Operation in the I/O Interface Mode (SCLK0 Input Mode)

#### ② Receiving data

#### SCLK output mode

In the SCLK output mode, if SC0MOD2  $\langle WBUF \rangle = "0"$  and receive double buffering is disabled, a synchronous clock pulse is output from the SCLK0 pin and the next data is shifted into receive buffer 1 each time the CPU reads received data. When all the 8 bits are received, the INTRX0 interrupt is generated.

The first SCLK output can be started by setting the receive enable bit SC0MOD0 <RXE> to "1." If the receive double buffering is enabled with SC0MOD2 <WBUF> set to "1," the first frame received is moved to receive buffer 2 and receive buffer 1 can receive the next frame successively. As data is moved from receive buffer 1 to receive buffer 2, the receive buffer full flag SC0MOD2 <RBFULL> is set to "1" and the INTRX0 interrupt is generated.

While data is in receive buffer 2, if CPU/DMAC cannot read data from receive buffer 2 in time before completing reception of the next 8 bits, the INTRX0 interrupt is not generated and the SCLK0 clock stops. In this state, reading data from receive buffer 2 allows data in receive buffer 1 to move to receive buffer 2 and thus the INTRX0 interrupt is generated and data reception resumes.

<WBUF> = "0" (if double buffering is disabled)

<WBUF> = "1" (if double buffering is enabled) (if data is read from buffer 2)

#### SCLK input mode

In the SCLK input mode, since receive double buffering is always enabled, the received frame can be moved to receive buffer 2 and receive buffer 1 can receive the next frame successively.

The INTRX receive interrupt is generated each time received data is moved to received buffer 2.

(Note) To receive data, SC0MOD <RXE> must always be set to "1" (receive enable) regardless of the SCLK input or output mode.

#### ③ Send and receive (full-duplex)

The full-duplex mode is enabled by setting bit 6 <FDPX0> of the serial mode control register 1 (SC0MOD1) to "1."

#### SCLK output mode

In the SCLK output mode, if SCOMOD2 <WBUF> is set to "0" and both the send and receive double buffers are disabled, SCLK is output when the CPU writes data to the send buffer. Subsequently, 8 bits of data are shifted into receive buffer 1 and the INTRX0 receive interrupt is generated. Concurrently, 8 bits of data written to the send buffer are output from the TXD0 pin, the INTTX0 send interrupt is generated when transmission of all data bits has been completed. Then, the SCLK output stops. In this, the next round of data transmission and reception starts when the data is read from the receive buffer and the next send data is written to the send buffer by the CPU. The order of reading the receive buffer and writing to the send buffer can be freely determined. Data transmission is resumed only when both conditions are satisfied.

If SC0MOD2 <WBUF> = "1" and double buffering is enabled for both transmission and reception, SCLK is output when the CPU writes data to the send buffer. Subsequently, 8 bits of data are shifted into receive buffer 1, moved to receive buffer 2, and the INTRX0 interrupt is generated. While 8 bits of data is received, 8 bits of transmit data is output from the TXD0 pin. When all data bits are sent out, the INTTX0 interrupt is generated and the next data is moved from the send buffer 2 to send buffer 1. If send buffer 2 has no data to be moved to send buffer 1 (SC0MOD2 <TBEMP> = 1) or when receive buffer 2 is full (SC0MOD2 <RBFULL> = 1), the SCLK clock is stopped. When both conditions are satisfied, i.e., receive data is read and send data is written, the SCLK output is resumed and the next round of data transmission is started.

<WBUF> = "0" (if double buffering is disabled)

Fig. 13.5.1.5 Send/Receive Operation in the I/O Interface Mode (SCLK0 Output Mode)

#### SCLK input mode

In the SCLK input mode with SCOMOD2 <WBUF> set to "0" and the send double buffers are disabled (double buffering is always enabled for the receive side), 8-bit data written in the send buffer is output from the TXD0 pin and 8 bits of data is shifted into the receive buffer when the SCLK0 input becomes active. The INTTX0 interrupt is generated upon completion of data transmission and the INTRX0 interrupt is generated at the instant the received data is moved from receive buffer 1 to receive buffer 2. Note that transmit data must be written into the send buffer before the SCLK input for the next frame (data must be written before the point A in Fig. 13.5.1.6). As double buffering is enabled for data reception, data must be read before completing reception of the next frame data.

If SC0MOD2 <WBUF> = "1" and double buffering is enabled for both transmission and reception, the interrupt INTRX0 is generated at the timing send buffer 2 data is moved to send buffer 1 after completing data transmission from send buffer 1. At the same time, the 8 bits of data received is shifted to buffer 1, moved to receive buffer 2, and the INTRX0 interrupt is generated. Upon the SCLK input for the next frame, transmission from send buffer 1 (in which data has been moved from send buffer 2) is started while receive data is shifted into receive buffer 1 simultaneously. If data in receive buffer 2 has not been read when the last bit of the frame is received, an overrun error occurs. Similarly, if there is no data written to send buffer 2 when SCLK for the next frame is input, an under-run error occurs.

<WBUF> = "0" (if double buffering is disabled)

<WBUF> = "1" (if double buffering is enabled) (no errors)

<WBUF> = "1" (if double buffering is enabled) (error generation)

Fig. 13.5.1.6 Send/Receive Operation in the I/O Interface Mode (SCLK0 Input Mode)

#### 13.5.2 Mode 1 (7-bit UART Mode)

The 7-bit UART mode can be selected by setting the serial mode control register (SC0MOD <SM1, 0>) to "01."

In this mode, parity bits can be added to the transmit data stream; the serial mode control register (SC0CR  $\langle PE \rangle$ ) controls the parity enable/disable setting. When  $\langle PE \rangle$  is set to "1" (enable), either even or odd parity may be selected using the SC0CR  $\langle EVEN \rangle$  bit. The length of the stop bit can be specified using SC0MOD2 $\langle$ SBLEN $\rangle$ .

Example: The control register settings for transmitting in the following data format are listed in the following table.

#### 13.5.3 Mode 2 (8-bit UART Mode)

The 8-bit UART mode can be selected by setting SC0MOD0  $\langle$ SM1:0 $\rangle$  to "10." In this mode, parity bits can be added and parity enable/disable is controlled using SC0CR  $\langle$ PE $\rangle$ . If  $\langle$ PE $\rangle$  = "1" (enabled), either even or odd parity can be selected using SC0CR  $\langle$ EVEN $\rangle$ .

Example: The control register settings for receiving data in the following format are as follows:

Main routine settings

7 6 5 4 3 2 1 0	
ר _ PCCR ← 0	
PCFC $\leftarrow _ _ _ _ _ 1 _ $	Designates PC1 as the RXD0 pin.
SCOMOD $\leftarrow$ _ 0 0 X 1 0 0 1	Selects the 8-bit UART mode.
SC0CR ← X 0 1 X X X 0 0	Sets odd parity.
BR0CR ← 0 0 0 1 0 1 0 1	Sets the data rate to 9600 bps.
IMC3 $\leftarrow$ 1 1 _ 0 1 0 0	Enables the INTRX0 interrupt and sets to level 4 by the <23:16>
	bits of the 32 bit register.
SCOMOD $\leftarrow$ 1 X	Enables reception of data.

An example interrupt routine process

Clears the interrupt request. 0x0000_0038 Performs error check Reads received data.

### 13.5.4 Mode 3 (9-bit UART)

The 9-bit UART mode can be selected by setting SC0MOD0  $\langle$ SM1:0 $\rangle$  to "11." In this mode, parity bits must be disabled (SC0CR  $\langle$ PE $\rangle$  = "0").

The most significant bit (9th bit) is written to bit 7 <TB8> of the serial mode control register 0 (SC0MOD0) for transmit data and it is stored in bit 7 <RB8> of the serial control register SC0CR upon receiving data. When writing or reading data to/from the buffers, the most significant bit must be written or read first before writing or reading to/from SC0BUF. The stop bit length can be specified using SC0MOD2 <SBLEN>.

#### Wakeup function

In the 9-bit UART mode, slave controllers can be operated in the wake-up mode by setting the wake-up function control bit SC0MOD0  $\langle$ WU $\rangle$  to "1." In this case, the interrupt INTRX0 will be generated only when SC0CR  $\langle$ RB8 $\rangle$  is set to "1."

# (Note) The TXD pin of the slave controller must be set to the open drain output mode using the ODE register.

Fig. 13.5.4.1 Serial Links to Use Wake-up Function

Protocol

- ① Select the 9-bit UART mode for the master and slave controllers.
- ② Set SC0MOD <WU> to "1" for the slave controllers to make them ready to receive data.
- ③ The master controller is to send a single frame of data that includes the slave controller select code (8 bits). In this, the most significant bit (bit 8) <TB8> must be set to "1."

- ④ Every slave controller receives the above data frame; if the code received matches with the controller's own select code, it clears the WU bit to "0."
- S The master controller transmits data to the designated slave controller (the controller of which SCOMOD <WU> bit is cleared to "0"). In this, the most significant bit (bit 8) <TB8> must be set to "0."

The slave controllers with the <WU> bit set to "1" ignore the receive data because the most significant bit (bit 8) <RB8> is set to "0" and thus no interrupt (INTRX0) is generated.

Also, the slave controller with the <WU> bit set to "0" can transmit data to the master controller to inform that the data has been successfully received.

Example setting: Using the internal clock fsys/2 as the transfer clock, two slave controllers are serially linked as follows:

① Master controller setting

Main routine

PCCR PCFC	$\begin{array}{c} \leftarrow & _ & _ & _ & _ & _ & _ & 0 & 1 \\ \leftarrow & _ & _ & _ & _ & _ & 1 & 1 \end{array}$	Besignates PC0/PC1 as the TXD0/RXD0 pins, respectively.
IMC3	$\leftarrow _ 1 1 _ 0 1 0 1$	Enables the INTRX0 interrupt and sets to level 5 by the <23:16> bits of the 32 bit register.
IIVIC3	$\leftarrow -11-0100$	Enables the INTTX0 interrupt and sets to level 4 by the <31:24> bits of the 32 bit register.
SC0MOD0	$\leftarrow$ 1 0 1 0 1 1 1 0	Sets the 9-bit UART mode and fsys/2 transfer clock.
SC0BUF	$\leftarrow 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 1$	Sets the select code of Slave 1.
Interrupt rou	utine (INTTX0)	
INTCLR	0 0 0 1 1 1 1 0 0	Clears the interrupt request. (0x0000_003C)
SC0MOD0	← 0	Sets TB8 to "0."
SC0BUF	← * * * * * * * * *	Sets the data to be sent.
Interrupt pr	ocessing is completed.	

② Slave controller setting

Main routine

PCCR	← 0 1 ך	
PCFC	← 1 1	- Designates PC0 as TXD (open drain output) and PC1 as RXD.
PCODE	← 1	
	$\leftarrow$ _ 1 1 _ 0 1 1 0	Enables INTTX0 and INTRX0.
IMC3	$\leftarrow$ _ 1 1 _ 0 1 0 1	
SC0MOD0	← 0 0 1 1 1 1 1 0	Sets the 9-bit UART mode and $f_{SYS}\!/\!2$ transfer clock and sets $<\!WU\!>$ to "1."
Interrupt rou	utine (INTRX0)	
INTCLR Reg.	0 0 0 1 1 1 0 0 0 ← SC0BUF	Clears the interrupt request.
if Reg. = se	elect code,	
Then		
SC0MOD0	$\leftarrow$ 0	Clears <wu> to "0."</wu>

# 14. Serial Bus Interface (SBI)

The TMP19A64 contains a Serial Bus Interface (SBI) channel, which has the following two operating modes:

- $I^2C$  bus mode (with multi-master capability)
- Clock-synchronous 8-bit SIO mode

In the I²C bus mode, the SBI is connected to external devices via PF0 (SDA) and PF1 (SCL). In the clocksynchronous 8-bit SIO mode, the SBI is connected to external devices via PF2 (SCK), PF0 (SO) and PF1 (SI).

The following table shows the	programming re	equired to put the	SBL in each operating mode
The following table shows the	programming R	quired to put the	SDI III cach operating mode.

	PFODE <pfode1:0></pfode1:0>	PFCR <pf2c, pf0c="" pf1c,=""></pf2c,>	PFFC <pf2f, pf0f="" pf1f,=""></pf2f,>
I2C bus mode	11	X11	011
Clock-synchronous 8-bit SIO mode	XX	101 (clock output) 001 (clock input)	111

X: Don't care

# 14.1 Configuration

The configuration is shown in Fig. 14.1.

Fig. 14.1 SBI Block Diagram

# 14.2 Control

The following registers control the serial bus interface and provide its status information for monitoring.

- Serial bus interface control register 0 (SBICR0)
- Serial bus interface control register 1 (SBICR1)
- Serial bus interface control register 2 (SBICR2)
- Serial bus interface buffer register (SBIDBR)
- I²C bus address register (I2CAR)
- Serial bus interface status register (SBISR)
- Serial bus interface baud rate register 0 (SBIBR0)

The functions of these registers vary, depending on the mode in which the SBI is operating. For a detailed description of the registers, refer to "14.5 Control in the  $I^2C$  Bus Mode" and "14.7 Control in the Clock-synchronous 8-bit SIO Mode."

# 14.3 I²C Bus Mode Data Formats

Fig. 14.3 shows the data formats used in the  $I^2C$  bus mode.

(a) Addressing format

(b) Addressing format (with repeated start condition)

(c) Free data format (master-transmitter to slave-receiver)

Note: S: Start condition

- $R/\overline{W}$ : Direction bit
- ACK: Acknowledge bit
  - P: Stop condition

Fig. 14.3 I²C Bus Mode Data Formats

# 14.4 Control Registers in the I²C Bus Mode

The following registers control the serial bus interface (SBI) in the  $I^2C$  bus mode and provide its status information for monitoring.

		7	6	5	4	3	2	1	0

Does not recognize slave address.

# 14.5 Control in the I²C Bus Mode

#### 14.5.1 Setting the Acknowledgement Mode

Setting SBICR1<ACK> to "1" selects the acknowledge mode. When operating as a master, the SBI adds one clock for acknowledgment signals. As a transmitter, the SBI releases the SDA pin during this clock cycle to receive acknowledgment signals from the receiver. As a receiver, the SBI pulls the SDA pin to the "L" level during this clock cycle and generates acknowledgment signals.

Setting <ACK> to "0" selects the non-acknowledgment mode. When operating as a master, the SBI does not generate clock for acknowledgement signals.

#### 14.5.2 Setting the Number of Bits per Transfer

SBICR1 <BC2:0> specifies the number of bits of the next data to be transmitted or received.

Under the start condition, <BC2:0> is set to "000," causing a slave address and the direction bit to be transferred in a packet of eight bits. At other times, <BC2:0> keeps a previously programmed value.

#### 14.5.3 Serial Clock

#### ① Clock source

SB SBICR1 <SCK2:0> specifies the maximum frequency of the serial clock to be output from the SCL pin in the master mode.

The highest speeds in the standard and high-speed modes are specified to 100 KHz and 400 KHz respectively in the communications standards. Note that the internal SCL clock frequency is determined by the fsys used and the calculation formula shown above.

#### ② Clock Synchronization

The  $I^2C$  bus is driven by using the wired-AND connection due to its pin structure. The first master that pulls its clock line to the "L" level overrides other masters producing the "H" level on their clock lines. This must be detected and responded by the masters producing the "H" level.

Clock synchronization assures correct data transfer on a bus that has two or more masters.

For example, the clock synchronization procedure for a bus with two masters is shown below.

Fig. 14.5.3.2 Example of Clock Synchronization

At point a, Master A pulls its internal SCL output to the "L" level, bringing the SCL bus line to the "L" level. Master B detects this transition, resets its "H" level period counter, and pulls its internal SCL output level to the "L" level.

Master A completes counting of its "L" level period at point b, and brings its internal SCL output to the "H" level. However, Master B still keeps the SCL bus line at the "L" level, and Master A stops counting of its "H" level period counting. After Master A detects that Master B brings its internal SCL output to the "H" level and brings the SCL bus line to the "H" level at point c, it starts counting of its "H" level period.

This way, the clock on the bus is determined by the master with the shortest "H" level period and the master with the longest "L" level period among those connected to the bus.

#### 14.5.4 Slave Addressing and Address Recognition Mode

When the SBI is configured to operate as a slave device, the slave address <SA6:0> and <ALS> must be set at I2CAR. Setting <ALS> to "0" selects the address recognition mode

### 14.5.5 Configuring the SBI as a Master or a Slave

Setting SBICR2<MST> to "1" configures the SBI to operate as a master device.

Setting  $\langle MST \rangle$  to "0" configures the SBI as a slave device.  $\langle MST \rangle$  is cleared to "0" by the hardware when the stop condition has been detected on the bus or when arbitration has been lost.

#### 14.5.6 Configuring the SBI as a Transmitter or a Receiver

Setting SBICR2 <TRX> to "1" configures the SBI as a transmitter. Setting <TRX> to "0" configures the SBI as a receiver.

In the slave mode, the SBI receives the direction bit ( R/W ) from the master device on the following occasions:

- when data is transmitted in the addressing format
- when the received slave address matches the value specified at I2CCR
- when a general-call address is received; i.e., the eight bits following the start condition are all zeros

If the value of the direction bit (R/W) is "1," <TRX> is set to "1" by the hardware. If the bit is "0," <TRX> is set to "0."

As a master device, the SBI receives acknowledgement from a slave device. If the direction bit of "1" is transmitted,  $\langle TRX \rangle$  is set to "0" by the hardware. If the direction bit is "0,"  $\langle TRX \rangle$  changes to "1." If the SBI does not receive acknowledgement,  $\langle TRX \rangle$  retains the previous value

<TRX> is cleared to "0" by the hardware when the stop condition has been detected on the bus or when arbitration has been lost.

#### 14.5.7 Generating Start and Stop Conditions

When SBISR<BB> is "0," writing "1" to SBICR2 <MST, TRX, BB, PIN> causes the SBI to generate the start condition on the bus and output 8-bit data. <ACK> must be set to "1" in advance.

When <BB> is "1," writing "1" to <MST, TRX, PIN> and "0" to <BB> causes the SBI to start a sequence for generating the stop condition on the bus. The contents of <MST, TRX, BB, PIN> should not be altered until the stop condition appears on the bus.

Fig. 14.5.7.2 Generating the Stop Condition

SBISR < BB > can be read to check the bus state. < BB > is set to "1" when the start condition is detected on the bus (the bus is busy), and set to "0" when the stop condition is detected (the bus is free).

#### 14.5.8 Interrupt Service Request and Release

When a serial bus interface interrupt request (INTSBI) is generated, SBICR2 <PIN> is cleared to "0." While <PIN> is "0," the SBI pulls the SCL line to the "L" level.

After transmission or reception of one data word, <PIN> is cleared to "0." It is set to "1" when data is written to or read from SBIDBR. It takes a period of  $t_{LOW}$  for the SCL line to be released after <PIN> is set to "1."

In the address recognition mode (<ALS> = "0"), <PIN> is cleared to "0" when the received slave address matches the value specified at I2CAR or when a general-call address is received; i.e., the eight bits following the start condition are all zeros. When the program writes "1" to SBICR2<PIN>, it is set to "1." However, writing "0" does clear this bit to "0."

#### 14.5.9 Serial Bus Interface Operating Modes

SBICR2 <SBIM1:0> selects an operating mode of the serial bus interface. <SBIM1:0> must be set to "10" to configure the SBI for the  $I^2C$  bus mode. Make sure that the bus is free before switching the operating mode to the port mode.

#### 14.5.10 Lost-arbitration Detection Monitor

The  $I^2C$  bus has the multi-master capability (there are two or more masters on a bus), and requires the bus arbitration procedure to ensure correct data transfer.

A master that attempts to generate the start condition while the bus is busy loses bus arbitration, with no start condition occurring on the SDA and SCL lines. The  $I^2C$ -bus arbitration takes place on the SDA line.

The arbitration procedure for two masters on a bus is shown below. Up until point a, Master A and Master B output the same data. At point a, Master A outputs the "L" level and Master B outputs the "H" level. Then Master A pulls the SDA bus line to the "L" level because the line has the wired-AND connection. When the SCL line goes high at point b, the slave device reads the SDA line data, i.e., data transmitted by Master A. At this time, data transmitted by Master B becomes invalid. In other words, Master B loses arbitration. Master B releases its SDA pin, so that it does not affect the data transfer initiated by another master. If two or more masters have transmitted exactly the same first data word, the arbitration procedure continues with the second data word.

Fig. 14.5.10.1 Lost Arbitration

A master compares the SDA bus line level and the internal SDA output level at the rising of the SCL line. If there is a difference between these two values, the master loses arbitration and sets SBI0SR <AL> to "1."

When <AL> is set to "1," SBISR <MST, TRX> are cleared to "0," causing the SBI to operate as a slave receiver. <AL> is cleared to "0" when data is written to or read from SBIDBR or data is written to SBICR2.

Fig. 14.5.10.2 Example of Master B Losing Arbitration (D7A = D7B, D6A = D6B)

#### 14.5.11 Slave Address Match Detection Monitor

When the SBI operates as a slave device in the address recognition mode (I2CCR  $\langle ALS \rangle = "0"$ ), SBISR  $\langle AAS \rangle$  is set to "1" on receiving the general-call address or the slave address that matches the value specified at I2CCR. When  $\langle ALS \rangle$  is "1,"  $\langle AAS \rangle$  is set to "1" when the first data word has been received.  $\langle AAS \rangle$  is cleared to "0" when data is written to or read from SBIDBR.

#### 14.5.12 General-call Detection Monitor

When the SBI operates as a slave device, SBISR  $\langle AD0 \rangle$  is set to "1" when it receives the general-call address; i.e., the eight bits following the start condition are all zeros.  $\langle AD0 \rangle$  is cleared to "0" when the start or stop condition is detected on the bus.

#### 14.5.13 Last Received Bit Monitor

SBISR <LRB> is set to the SDA line value that was read at the rising of the SCL line. In the acknowledgment mode, reading SBISR <LRB> immediately after generation of the INTSBI interrupt request causes ACK signal to be read.

### 14.5.14 Software Reset

If the serial bus interface circuit locks up due to external noise, it can be initialized by using a software reset.

Writing "10" followed by "01" to SBICR2 <SWRST1:0> generates a reset signal that initializes the serial bus interface circuit. After a reset, all control registers and status flags are initialized to their reset values. When the serial bus interface is initialized, <SWRST> is automatically cleared to "0."

(Note) After a software reset, the operating mode is also reset from the I²C mode to the synchronous communication mode.

#### 14.5.15 Serial Bus Interface Data Buffer Register (SBIDBR)

Reading or writing SBIDBR initiates reading received data or writing transmitted data. When the SBI is acting as a master, setting a slave address and a direction bit to this register generates the start condition.

### 14.5.16 I²C Bus Address Register (I2CAR)

When the SBI is configured as a slave device, the I2CAR $\leq$ SA6:0> bit is used to specify a slave address. If I2C0AR  $\leq$ ALS> is set to "0," the SBI recognizes a slave address transmitted by the master device and receives data in the addressing format. If  $\leq$ ALS> is set to "1," the SBI does not recognize a slave address and receives data in the free data format.

### 14.5.17 IDLE Setting Register (SBIBR0)

The SBIBR0<I2SBI> register determines if the SBI operates or not when it enters the IDLE mode. This register must be programmed before executing an instruction to switch to the standby mode.

# 14.6 Data Transfer Procedure in the I²C Bus Mode

#### 14.6.1 Device Initialization

First, program SBICR1<ACK, SCK2:0> by writing "0" to bits 7 to 5 and bit 3 in SBICR1.

Next, program I2CAR by specifying a slave address at <SA6:0> and an address recognition mode at <ALS>. (<ALS> must be set to "0" when using the addressing format.)

Next, program SBICR2 to initially configure the SBI in the slave receiver mode by writing "0" to <MST, TRX, BB>, "1" to <PIN>, "10" to <SBIM1:0> and "0" to bits 1 and 0.

Specifies ACK and SCL clock. Specifies a slave address and an address recognition mode. Configures the SBI as a slave receiver.

#### 14.6.2 Generating the Start Condition and a Slave Address

① Master mode

In the master mode, the following steps are required to generate the start condition and a slave address.

First, ensure that the bus is free ( $\langle BB \rangle = "0"$ ). Then, write "1" to SBICR1  $\langle ACK \rangle$  to select the acknowledgment mode. Write to SBIDBR a slave address and a direction bit to be transmitted.

When  $\langle BB \rangle = "0,"$  writing "1111" to SBICR2  $\langle MST, TRX, BB, PIN \rangle$  generates the start condition on the bus. Following the start condition, the SBI generates nine clocks from the SCL pin. The SBI outputs the slave address and the direction bit specified at SBIDBR with the first eight clocks, and releases the SDA line in the ninth clock to receive an acknowledgment signal from the slave device.

The INTSBI interrupt request is generated on the falling of the ninth clock, and <PIN> is cleared to "0." In the master mode, the SBI holds the SCL line at the "L" level while <PIN> is "0." <TRX> changes its value according to the transmitted direction bit at generation of the INTSBI interrupt request, provided that an acknowledgment signal has been returned from the slave device.

Example of INTSBI interrupt routine

INTCLR  $\leftarrow$  0x50 Processing End of interrupt Ensures that the bus is free.

Selects the acknowledgement mode. Specifies the desired slave address and direction. Generates the start condition.

Clears the interrupt request.

② Slave mode

In the slave mode, the SBI receives the start condition and a slave address.

After receiving the start condition from the master device, the SBI receives a slave address and a direction bit from the master device during the first eight clocks on the SCL line. If the received address matches its slave address specified at I2CAR or is equal to the general-call address, the SBI pulls the SDA line to the "L" level during the ninth clock and outputs an acknowledgment signal.

The INTSBI interrupt request is generated on the falling of the ninth clock, and <PIN> is cleared to "0." In the slave mode, the SBI holds the SCL line at the "L" level while <PIN> is "0."

#### 14.6.3 Transferring a Data Word

At the end of a data word transfer, the INTSBI interrupt is generated to test <MST> to determine whether the SBI is in the master or slave mode.

① Master mode ( $\langle MST \rangle = "1"$ )

Test <TRX> to determine whether the SBI is configured as a transmitter or a receiver.

Transmitter mode (<TRX> = "1")

Test <LRB>. If <LRB> is "1," that means the receiver requires no further data. The master then generates the stop condition as described later to stop transmission.

If <LRB> is "0," that means the receiver requires further data. If the next data to be transmitted has eight bits, the data is written into SBIDBR. If the data has different length, <BC2:0> and <ACK> are programmed and the transmit data is written into SBIDBR. Writing the data makes <PIN> to"1," causing the SCL pin to generate a serial clock for transfer of a next data word, and the SDA pin to transfer the data word. After the transfer is completed, the INTSBI interrupt request is generated, <PIN> is set to "0," and the SCL pin is pulled to the "L" level. To transmit more data words, test <LRB> again and repeat the above procedure.

INTSBI interrupt reque	st
	Master to slave     – – – Slave to master

Fig. 14.6.3.1 <BC2:0> = "000" and <ACK> = "1" (Transmitter Mode)

#### Receiver mode (<TRX> = "0")

If the next data to be transmitted has eight bits, the transmit data is written into SBIDBR. If the data has different length, <BC2:0> and <ACK> are programmed and the received data is read from SBIDBR to release the SCL line. (The data read immediately after transmission of a slave address is undefined.) On reading the data, <PIN> is set to "1," and the serial clock is output to the SCL pin to transfer the next data word. In the last bit, when the acknowledgment signal becomes the "L" level, "0" is output to the SDA pin.

After that, the INTSBI interrupt request is generated, and <PIN> is cleared to "0," pulling the SCL pin to the "L" level. Each time the received data is read from SBIDBR, one-word transfer clock and an acknowledgement signal are output.

#### Fig. 14.6.3.2 <BC2:0> = "000" and <ACK> = "1" (Receiver Mode)

To terminate the data transmission from the transmitter, <ACK> must be set to "0" immediately before reading the second to last data word. This disables generation of an acknowledgment clock for the last data word. When the transfer is completed, an interrupt request is generated. After the interrupt processing, <BC2:0> must be set to "001" and the data must be read so that a clock is generated for 1-bit transfer. At this time, the master receiver holds the SDA bus line at the "H" level, which signals the end of transfer to the transmitter as an acknowledgment signal.

In the interrupt processing for terminating the reception of 1-bit data, the stop condition is generated to terminate the data transfer.

Fig. 14.6.3.3 Terminating Data Transmission in the Master Receiver Mode

Example: When receiving N data words

INTSBI interrupt (after data transmission) 7 6 5 4 3 2 1 0 ← X X X X 0 X X X SBICR1 Sets the number of bits of data to be received and specify whether ACK is required. ← SBI0CBR Reg. Reads dummy data. End of interrupt INTSBI interrupt (first to (N-2)th data reception) 7 6 5 4 3 2 1 0 Reg. ← SBIDBR Reads the first to (N-2)th data words. End of interrupt INTSBI interrupt ((N-1)th data reception) 7 6 5 4 3 2 1 0 SBIOCR1  $\leftarrow$  X X X 0 0 X X X Disables generation of acknowledgement clock.  $\leftarrow$  SBIDBR Reg. Reads the (N-1)th data word. End of interrupt INTSBI interrupt (Nth data reception) 7 6 5 4 3 2 1 0 SBI0CR1  $\leftarrow$  0 0 1 0 0 X X X Generates a clock for 1-bit transfer. Reg. ← SBIDBR Reads the Nth data word. End of interrupt INTSBI interrupt (after completing data reception) Processing to generate the stop condition Terminates the data transmission. End of interrupt (Note) X: Don't care

#### ② Slave mode ( $\langle MST \rangle = "0"$ )

In the slave mode, the SBI generates the INTSBI interrupt request on four occasions: 1) when the SBI has received any slave address from the master, 2) when the SBI has received a general-call address, 3) when the received slave address matches its own address, and 4) when a data transfer has been completed in response to a general-call. Also, if the SBI loses arbitration in the master mode, it switches to the slave mode. Upon the completion of data word transfer in which arbitration is lost, the INTSBI interrupt request is generated,  $\langle PIN \rangle$  is cleared to "0," and the SCL pin is pulled to the "L" level. When data is written to or read from SBIDBR or when  $\langle PIN \rangle$  is set to "1," the SCL pin is released after a period of  $t_{LOW}$ .

In the slave mode, the normal slave mode processing or the processing as a result of lost arbitration is carried out.

SBISR <AL>, <TRX>, <AAS> and <AD0> are tested to determine the processing required. Table 14.6.3.4 shows the slave mode states and required processing.

Example: When the received slave address matches the SBI's own address and the direction bit is "1" in the slave receiver mode

INTSBI interrupt if TRX = 0 Then go to other processing if AL = 1 Then go to other processing if AAS = 0 Then go to other processing SBICR1  $\leftarrow$  X X X 1 0 X X X SBIDBR  $\leftarrow$  X X X X 0 X X X

Sets the number of bits to be transmitted. Sets the transmit data.

(Note) X: Don't care

<trx></trx>	<al></al>	<aas></aas>	<ad0></ad0>	State	Processing
1	1	1	0	Arbitration was lost while the slave address was being transmitted, and the SBI received a slave address with the direction bit "1" transmitted by another master.	Set the number of bits in a data word to <bc2:0> and write the transmit data into SBI0DBR.</bc2:0>
	0	1	0	In the slave receiver mode, the SBI received a slave address with the direction bit "1" transmitted by the master.	
		0	0	In the slave transmitter mode, the SBI has completed a transmission of one data word.	Test LRB. If it has been set to "1," that means the receiver does not require further data. Set $<$ PIN> to 1 and reset $<$ TRX> to 0 to release the bus. If $<$ LRB> has been reset to "0," that means the receiver requires further data. Set the number of bits in the data word to $<$ BC2:0> and write the transmit data to the SBIDBR.
0	1	1	1/0	Arbitration was lost while a slave address was being transmitted, and the SBI received either a slave address with the direction bit "0" or a general- call address transmitted by another master.	Read the SBIDBR (a dummy read) to set <pin> to 1, or write "1" to <pin>.</pin></pin>
		0	0	Arbitration was lost while a slave address or a data word was being transmitted, and the transfer terminated.	
	0	1	1/0	In the slave receiver mode, the SBI received either a slave address with the direction bit "0" or a general-call address transmitted by the master.	
		0	1/0	In the slave receiver mode, the SBI has completed a reception of a data word.	Set the number of bits in the data word to <bc2:0> and read the received data from SBIDBR.</bc2:0>

Table 14.6.3.4 Processing in Slave Mode

### 14.6.4 Generating the Stop Condition

When SBISR <BB> is "1," writing "1" to SBICR2 <MST, TRX, PIN> and "0" to <BB> causes the SBI to start a sequence for generating the stop condition on the bus. Do not alter the contents of <MST, TRX, BB, PIN> until the stop condition appears on the bus.

If another device is holding down the SCL bus line, the SBI waits until the SCL line is released. After that, the SDA pin goes high, causing the stop condition to be generated.

Fig. 14.6.4.1 Generating the Stop Condition

#### 14.6.5 Repeated Start Procedure

Repeated start is used when a master device changes the data transfer direction without terminating the transfer to a slave device. The procedure of generating a repeated start in the master mode is described below.

First, set SBICR2 <MST, TRX, BB> to "0" and write "1" to <PIN> to release the bus. At this time, the SDA pin is held at the "H" level and the SCL pin is released. Because no stop condition is generated on the bus, other devices think that the bus is busy. Then, test SBISR <BB> and wait until it becomes "0" to ensure that the SCL pin is released. Next, test <LRB> and wait until it becomes "1" to ensure that no other device is pulling the SCL bus line to the "L" level. Once the bus is determined to be free this way, use the steps described above in (2) to generate the start condition.

To satisfy the setup time of repeated start, at least 4.7- $\mu$ s wait period (in the standard mode) must be created by the software after the bus is determined to be free.

7 6 5 4 3 2 1 0 SBICR2 ← 0 0 0 1 1 0 0 0 Releases the bus. Checks that the SCL pin is released. if SBISR<BB> ≠ 0 Then if SBISR<LRB> ≠ 1 Checks that no other device is pulling the SCL pin to the "L" level. Then 4.7 µs Wait  $\leftarrow X X X 1 0 X X X$ SBICR1 Selects the acknowledgment mode. SBIDBR Sets the desired slave address and direction. SBICR2  $\leftarrow$  1 1 1 1 1 0 0 0 Generates the start condition. (Note) X: Don't care "0" → <MST> "1"  $\rightarrow \langle MST \rangle$ "0"  $\rightarrow \langle TRX \rangle$ "1" → <TRX> "0" → <BB> "1" → <BB> "1" → <PIN> "1" → <PIN> – 4.7 μs (min.) Start condition SCL (bus) q SCL pin SDA pin <LRB> <BB> <PIN>

(Note) Do not write <MST> to "0" when it is "0." (Repeated start cannot be done.)

## 14.7 Control in the Clock-synchronous 8-bit SIO Mode

The following registers control the serial bus interface in the clock-synchronous 8-bit SIO mode and provide its status information for monitoring.

#### 14.7.1 Serial Clock

#### ① Clock source

Internal or external clocks can be selected by programming SBICR1 <SCK2:0>.

#### Internal clocks

In the internal clock mode, one of the seven frequencies can be selected as a serial clock, which is output to the outside through the SCK pin. At the beginning of a transfer, the SCK pin output becomes the "H" level.

If the program cannot keep up with this serial clock rate in writing the transmit data or reading the received data, the SBI automatically enters a wait period. During this period, the serial clock is stopped automatically and the next shift operation is suspended until the processing is completed.

Fig. 14.7.1.3 Automatic Wait

#### External clock (<SCK2:0> = "111")

The SBI uses an external clock supplied from the outside to the SCK pin as a serial clock. For proper shift operations, the serial clock at the "H" and "L" levels must have the pulse widths as shown below.

Fig. 14.7.1.4 Maximum Transfer Frequency of External Clock Input

#### ② Shift Edge

Leading-edge shift is used in transmission. Trailing-edge shift is used in reception.

#### Leading-edge shift

Data is shifted at the leading edge of the serial clock (or the falling edge of the SCK pin input/output).

#### Trailing-edge shift

Data is shifted at the trailing edge of the serial clock (or the rising edge of the SCK pin input/output).

Fig. 14.7.1.5 Shift Edge

#### 14.7.2 Transfer Modes

The transmit mode, the receive mode or the transmit/receive mode can be selected by programming SBICR1 <SIOM1:0>.

① 8-bit transmit mode

INT

Set the control register to the transmit mode and write the transmit data to SBIDBR.

After writing the transmit data, writing "1" to SBICR1 <SIOS> starts the transmission. The transmit data is moved from SBIDBR to a shift register and output to the SO pin, with the least-significant bit (LSB) first, in synchronization with the serial clock. Once the transmit data is transferred to the shift register, SBIDBR becomes empty, and the INTSBI (buffer-empty) interrupt is generated, requesting the next transmit data.

In the internal clock mode, the serial clock will be stopped and automatically enter the wait state, if next data is not loaded after the 8-bit data has been fully transmitted. The wait state will be cleared when SBIDBR is loaded with the next transmit data.

In the external clock mode, SBIDBR must be loaded with data before the next data shift operation is started. Therefore, the data transfer rate varies depending on the maximum latency between when the interrupt request is generated and when SBIDBR is loaded with data in the interrupt service program.

At the beginning of transmission, the same value as in the last bit of the previously transmitted data is output in a period from setting SBISR <SIOF> to "1" to the falling edge of SCK.

Transmission can be terminated by clearing  $\langle SIOS \rangle$  to "0" or setting  $\langle SIOINH \rangle$  to "1" in the INTSBI interrupt service program. If  $\langle SIOS \rangle$  is cleared, remaining data is output before transmission ends. The program checks SBI0SR  $\langle SIOF \rangle$  to determine whether transmission has come to an end.  $\langle SIOF \rangle$  is cleared to "0" at the end of transmission. If  $\langle SIOINH \rangle$  is set to "1," the transmission is aborted immediately and  $\langle SIOF \rangle$  is cleared to "0."

In the external clock mode, <SIOS> must be set to "0" before the next transmit data shift operation is started. Otherwise, operation will stop after dummy data is transmitted.

SBICR1	←	-	-	-	4 0	-	_		-	Selects the transmit mode.	
SBIDBR SBICR1										Writes the transmit data. Starts transmission.	
interrupt SBIDBR	←	х	х	х	х	х	х	х	х	Writes the transmit data.

		STB	r3, (SBICR1) ; $\langle SIOS \rangle \leftarrow 0$	

Fig. 14.7.2.2 Transmit Data Retention Time at the End of Transmission

② 8-bit receive mode

Set the control register to the receive mode. Then writing "1" to SBICR1 <SIOS> enables reception. Data is taken into the shift register from the SI pin, with the least-significant bit (LSB) first, in synchronization with the serial clock. Once the shift register is loaded with the 8-bit data, it transfers the received data to SBIDBR and the INTSBI (buffer-full) interrupt request is generated to request reading the received data. The interrupt service program then reads the received data from SBIDBR.

In the internal clock mode, the serial clock will be stopped and automatically be in the wait state until the received data is read from SBIDBR.

In the external clock mode, shift operations are executed in synchronization with the external clock. The maximum data transfer rate varies, depending on the maximum latency between generating the interrupt request and reading the received data.

Reception can be terminated by clearing <SIOS> to "0" or setting <SIOINH> to "1" in the INTSBI interrupt service program. If <SIOS> is cleared, reception continues until all the bits of received data are written to SBIDBR. The program checks SBISR <SIOF> to determine whether reception has come to an end. <SIOF> is cleared to "0" at the end of reception. After confirming the completion of the reception, last received data is read. If <SIOINH> is set to "1," the reception is aborted immediately and <SIOF> is cleared to "0." (The received data becomes invalid, and there is no need to read it out.)

#### (Note) The contents of SBIDBR will not be retained after the transfer mode is changed. The ongoing reception must be completed by clearing <SIOS> to "0" and the last received data must be read before the transfer mode is changed.

SBICR1	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	Selects the receive mode.
SBICR1	$\leftarrow$ 1 0 1 1 0 0 0 0	Starts reception.
INTSBI interro	-	- 
Reg.	← SBIDBR	Reads the received data.

Fig. 14.7.2.3 Receive Mode (Example: Internal Clock)

③ 8-bit transmit/receive mode

Set the control register to the transfer/receive mode. Then writing the transmit data to SBIDBR and setting SBICR1 <SIOS> to "1" enables transmission and reception. The transmit data is output through the SO pin at the falling of the serial clock, and the received data is taken in through the SI pin at the rising of the serial clock, with the least-significant bit (LSB) first. Once the shift register is loaded with the 8-bit data, it transfers the received data to SBIDBR and the INTSBI interrupt request is generated. The interrupt service program reads the received data from the data buffer register and writes the next transmit data. Because SBIDBR is shared between transmit and receive operations, the received data must be read before the next transmit data is written.

In the internal clock operation, the serial clock will be automatically in the wait state until the received data is read and the next transmit data is written.

In the external clock mode, shift operations are executed in synchronization with the external serial clock. Therefore, the received data must be read and the next transmit data must be written before the next shift operation is started. The maximum data transfer rate for the external clock operation varies depending on the maximum latency between generating the interrupt request and reading the received data and writing the transmit data.

At the beginning of transmission, the same value as in the last bit of the previously transmitted data is output in a period from setting <SIOF> to "1" to the falling edge of SCK.

Transmission and reception can be terminated by clearing <SIOS> to "0" or setting SBICR1 <SIOINH> to "1" in the INTSBI interrupt service program. If <SIOS> is cleared, transmission and reception continue until the received data is fully transferred to SBIDBR. The program checks SBISR <SIOF> to determine whether transmission and reception have come to an end. <SIOF> is cleared to "0" at the end of transmission and reception. If <SIOINH> is set, the transmission and reception are aborted immediately and <SIOF> is cleared to "0."

(Note) The contents of SBIDBR will not be retained after the transfer mode is changed. The ongoing transmission and reception must be completed by clearing <SIOS> to "0" and the last received data must be read before the transfer mode is changed.

Fig. 14.7.2.4 Transmit/Receive Mode (Example: Internal Clock)

SBICR1	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	Selects the transmit mode.
	$\begin{array}{c} \leftarrow X X X X X X X X X X X \\ \leftarrow 1 0 1 0 0 X X X \end{array}$	Writes the transmit data. Starts reception/transmission.
0	$ \begin{array}{l} \text{ipt} \\ \leftarrow \text{SBIODBR} \\ \leftarrow \text{X X X X X X X X} \end{array} $	Reads the received data. Writes the transmit data.

# 15. Analog/Digital Converter

A 10-bit, sequential-conversion analog/digital converter (A/D converter) is built into the TMP19A64. This A/D converter is equipped with 24 analog input channels.

Fig. 15.1 shows the block diagram of this A/D converter.

These 24 analog input channels (pins AN0 through AN23) are also used as input ports.

#### (Note) If it is necessary to reduce a power current by operating the TMP19A64 in IDLE, SLEEP, SLOW or STOP mode and if either case shown below is applicable, you must first stop the A/D converter and then execute the instruction to put the TMP19A64 into standby mode:

1) The TMP19A64 must be put into IDLE mode when ADMOD1<I2AD> is "0."

2) The TMP19A64 must be put into SLEEP, SLOW or STOP mode.

Fig. 15.1 A/D Converter Block Diagram

# 15.1 Control Register

The A/D converter is controlled by A/D mode control registers (ADMOD0, ADMOD1, ADMOD2, ADMOD3 and ADMOD4). Results of A/D conversion are stored in 16 upper and lower A/D conversion result registers ADREG08H/L through ADREG7FH/L. Results of High-priority conversion are stored in ADREGSPH/L.

Fig. 15.1.1 shows the registers related to the A/D converter.

### **15.3 Description of Operations**

#### 15.3.1 Analog Reference Voltage

The "H" level of the analog reference voltage shall be applied to the VREFH pin, and the "L" level shall be applied to the VREFL pin. By writing "0" to the ADMOD1<VREFON> bit, a switched-on state of VREFH-VREFL can be turned into a switched-off state. To start AD conversion, make sure that you first write "1" to the <VREFON> bit, wait for 3 µs during which time the internal reference voltage should stabilize, and then write "1" to the ADMOD0<ADS> bit.

### 15.3.2 Selecting the Analog Input Channel

How the analog input channel is selected is different depending on A/D converter operation mode used.

- (1) Normal AD conversion mode
  - If the analog input channel is used in a fixed state (ADMOD0<SCAN>="0"): One channel is selected from analog input pins AIN0 through AIN23 by setting ADMOD1<ADCH4 to 0> to an appropriate setting.
  - If the analog input channel is used in a scan state (ADMOD0<SCAN>="1"):

One scan mode is selected from 24 scan modes by setting ADMOD1<ADCH4 to 0> and ADSCN to appropriate settings.

(2) High-priority AD conversion mode

One channel is selected from analog input pins AIN0 through AIN23 by setting ADMOD2<HPADCH4 to 0> to an appropriate setting.

After a reset, ADMOD0<SCAN> is initialized to "0" and ADMOD1<ADCH3:0> is initialized to "0000." This initialization works as a trigger to select a fixed channel input through the AN0 pin. The pins that are not used as analog input channels can be used as ordinary input ports.

If High-priority AD conversion is activated during normal AD conversion, normal AD conversion is discontinued, High-priority AD conversion is executed and completed, and then normal AD conversion is resumed.

Example: A case in which repeat-scan conversion is ongoing at channels AIN0 through AIN3 with ADMOD0<REPEAT:SCAN> set to "11" and ADMOD1<ADCH4:0> set to 00011, and High-priority AD conversion has been activated at AIN15 with ADMOD2<HPADCH4:0>=01111:

Top-priority AD has	been activ	rated						
	/							_
Conversion Ch (	Ch0	Ch1	Ch2	Ch15	Ch2	Ch3	Ch0	
	/							

### 15.3.3 Starting A/D Conversion

Two types of A/D conversion are supported: normal AD conversion and High-priority AD conversion. Normal AD conversion is software activated by setting ADMOD0<ADS> to "1." High-priority AD conversion is software activated by setting ADMOD2<HPADCE> to "1." 4 operation modes are made available to normal AD conversion. In performing normal AD conversion, one of these operation modes must be selected by setting ADMOD0<2:1> to an appropriate setting. For High-priority AD conversion, only one operation mode can be used: fixed channel single conversion mode. Normal AD conversion can be activated using the HW activation source selected by ADMOD4<ADHS>, and High-priority AD conversion can be activated using the HW activation source selected by ADMOD4<HADHS>. If this bit is "0," normal AD conversion is activated in response to INTTB00 generated by the 16-bit timer 0, and High-priority AD conversion is activated in response to INTTB01 generated by the 16-bit timer 0, and High-priority AD conversion is activated in response to INTTB91 generated by the 16-bit timer 9. Software activation is still valid even after H/W activation has been authorized.

When normal A/D conversion starts, the A/D conversion Busy flag (ADMOD0<ADBF>) showing that A/D conversion is under way is set to "1." When High-priority A/D conversion starts, the A/D conversion Busy flag (ADMOD2<ADBFHP>) showing that A/D conversion is under way is set to "1." If normal A/D conversion is interrupted by High-priority A/D conversion, the value of the Busy flag for normal A/D conversion before the start of High-priority A/D conversion is retained. The value of the conversion can also be retained.

(Note) Normal A/D conversion must not be activated when High-priority A/D conversion is under way. If activated when High-priority A/D conversion is under way, the High-priority A/D conversion completion flag cannot be set, and the flag for previous normal A/D conversion cannot be cleared.

To reactivate normal A/D conversion, a software reset (ADMOD4<ADRST1:0>) must be performed before starting A/D conversion. The HW activation method must not be used to reactivate normal A/D conversion.

If ADMOD2<HPADCE> is set to "1" during normal A/D conversion, ongoing A/D conversion is discontinued and High-priority A/D conversion starts; specifically, A/D conversion (fixed channel single conversion) is executed for a channel designated by ADMOD2<3:0>. After the result of this High-priority A/D conversion is stored in the storage register ADREGSP, normal A/D conversion is resumed.

If HW activation of High-priority A/D conversion is authorized during normal A/D conversion, ongoing A/D conversion is discontinued when requirements for activation using a resource are met, and High-priority A/D conversion (fixed channel single conversion) starts for a channel designated by ADMOD2<3:0>. After the result of this High-priority A/D conversion is stored in the storage register ADREGSP, normal A/D conversion is resumed.

### 15.3.4 A/D Conversion Modes and A/D Conversion Completion Interrupts

For A/D conversion, the following four operation modes are supported. For normal A/D conversion, an operation mode can be selected by setting ADMOD0<2:1> to an appropriate setting. For High-priority A/D conversion, the fixed channel single conversion mode is automatically selected, irrespective of the ADMOD0<2:1> setting.

- Fixed channel single conversion mode
- Channel scan single conversion mode
- Fixed channel repeat conversion mode
- Channel scan repeat conversion mode
- (1) Normal A/D conversion

An operation mode is selected with ADMOD0<REPEAT, SCAN>. As A/D conversion starts, ADMOD0<ADBFN> is set to "1." When specified A/D conversion is completed, the A/D conversion completion interrupt (INTAD) is generated, and ADMOD0<EOCF> showing the completion of A/D conversion is set to "1." If <REPEAT>="0," <ADBFN> returns to "0" concurrently with the setting of EOCF. If <REPEAT> is set to "1," <ADBFN> remains at "1" and A/D conversion continues.

① Fixed channel single conversion mode

If ADMOD0 <REPEAT, SCAN> is set to "00," A/D conversion is performed in the fixed channel single conversion mode.

In this mode, A/D conversion is performed once for one channel selected. After A/D conversion is completed, ADMOD0<EOCF> is set to "1," ADMOD0<ADBF> is cleared to "0," and the interrupt request INTAD is generated. <EOCF> is cleared to "0" upon read.

^② Channel scan single conversion mode

If ADMOD0 <REPET,SCAN> is set to "01," A/D conversion is performed in the channel scan single conversion mode.

In this mode, A/D conversion is performed once for each scan channel selected. After A/D scan conversion is completed, ADMOD0<EOCF> is set to "1," ADMOD0<ADBF> is cleared to "0," and the interrupt request INTAD is generated. <EOCF> is cleared to "0" upon read.

③ Fixed channel repeat conversion mode

If ADMOD0<REPEAT,SCAN> is set to "10," A/D conversion is performed in fixed channel repeat conversion mode.

In this mode, A/D conversion is performed repeatedly for one channel selected. After A/D conversion is completed, ADMOD <EOCF> is set to "1." ADMOD0 <ADBF> is not cleared to "0." It remains at "1." The timing with which the interrupt request INTAD is generated can be selected by setting ADMOD0 <ITM1:0> to an appropriate setting. <EOCF> is set with the same timing as this interrupt INTAD is generated.

<EOCF> is cleared to "0" upon read.

With <ITM1:0> set to "00," an interrupt request is generated each time one A/D conversion is completed. In this case, the conversion results are always stored in the storage register ADREG08. After the conversion result is stored, EOCF changes to "1."

With <ITM1:0> set to "01," an interrupt request is generated each time four A/D conversion are completed. In this case, the conversion results are sequentially stored in storage registers ADREG08 through ADREG3B. After the conversion results are stored in ADREG3B, <EOCF> is set to "1," and the storage of subsequent conversion results starts from ADREG08. <EOCF> is cleared to "0" upon read.

With <ITM1:0> set to "10," an interrupt request is generated each time eight A/D conversions are completed. In this case, the conversion results are sequentially stored in storage registers ADREG08 through ADREG7F. After the conversion results are stored in ADREG7F, <EOCF> is set to "1," and the storage of subsequent conversion results starts from ADREG08.

<EOCF> is cleared to "0" upon read.

④ Channel scan repeat conversion mode

If ADMOD0 <REPEAT, SCAN> is set to "11," A/D conversion is performed in the channel scan repeat conversion mode.

In this mode, A/D conversion is performed repeatedly for a scan channel selected. Each time one A/D scan conversion is completed, ADMOD0 <EOCF> is set to "1," and the interrupt request INTAD is generated. ADMOD0 <ADBF> is not cleared to "0." It remains at "1." <EOCF> is cleared to "0" upon read.

To stop the A/D conversion operation in the repeat conversion mode (modes described in ③ and ④ above), write "0" to ADMODO <REPEAT>. When ongoing A/D conversion is completed, the repeat conversion mode terminates, and ADMODO <ADBF> is set to "0."

(2) High-priority A/D conversion

High-priority A/D conversion is performed only in fixed channel single conversion mode. The ADMOD0<REPEAT, SCAN> setting has no relevance to the High-priority A/D conversion operations or preparations. As activation requirements are met, A/D conversion is performed only once for a channel designated by ADMOD2<HPADCH3:0>. After the A/D conversion is completed, the High-priority A/D conversion completion interrupt is generated, ADMOD2<EOCFHP> is set to "1," and <ADBFHP> returns to "0." The EOCFHP Flag is cleared upon read.

Conversion mode	Interrupt generation	EOCF setting timing	ADBF	ADMOD0			
Conversion mode	timing	(see Note)	(after the interrupt is generated)	ITM1:0	REPEAT	SCAN	
Fixed channel single conversion	After conversion is completed	After conversion is completed	0		0	0	
Fixed channel repeat conversion	Each time one conversion is completed	After one conversion is completed	1	00			
	Each time four conversions are completed	After four conversions are completed	1	01	1	0	
	Each time eight conversions are completed	After eight conversions are completed	1	10			
Channel scan single conversion	After scan conversion is completed	After scan conversion is completed	1		0	1	
Channel scan repeat conversion	Each time one scan conversion is completed	After one scan conversion is completed	1		1	1	

Relationships between A/D Conversion Modes, Interrupt Generation Timings and Flag Operations

(Note) EOCF is cleared upon read.

Fig. 15.3.4.1 Relationships between A/D Conversion Modes, Interrupt Generation Timings and Flag Operations

### 15.3.5 High-priority Conversion Mode

By interrupting ongoing normal A/D conversion, High-priority A/D conversion can be performed. High-priority A/D conversion can be software activated by setting ADMOD2<HPADCE> to "1" or it can be activated using the HW resource by setting ADMOD4<7:6> to an appropriate setting. If High-priority A/D conversion has been activated during normal A/D conversion, ongoing normal A/D conversion is interrupted, and single conversion is performed for a channel designated by ADMOD2<3:0>. The result of single conversion is stored in ADREGSP, and the High-priority A/D conversion interrupt is generated. After High-priority A/D conversion is completed, normal A/D conversion is resumed; the status of normal A/D conversion immediately before being interrupted is maintained. High-priority A/D conversion activated while High-priority A/D conversion is under way is ignored.

For example, if channel repeat conversion is activated for channels AN0 through AN8 and if <HPADCE> is set to "1" during AN3 conversion, AN3 conversion is suspended, and conversion is performed for a channel designated by <HPADC3:0>. After the result of conversion is stored in ADREGSP, channel repeat conversion is resumed, starting from AN3.

### 15.3.6 A/D Monitor Function

If ADMOD3<ADOBSV> is set to "1," the A/D monitor function is enabled. If the value of the conversion result storage register specified by REGS<3:0> becomes larger or smaller ("larger" or "smaller" to be designated by ADOBIC) than the value of a comparison register, the A/D monitor function interrupt is generated. This comparison operation is performed each time a result is stored in a corresponding conversion result storage register, and the interrupt is generated if the conditions are met. Because storage registers assigned to perform the A/D monitor function are usually not read by software, overrun flag <OVRn> is always set and the conversion result storage flag <ADRnRF> is also set. To use the A/D monitor function, therefore, a flag of a corresponding conversion result storage register must not be used.

### 15.3.7 A/D Conversion Time

By setting ADCLK<ADCLK2:0> to an appropriate setting, one A/D conversion clock can be selected for fc, fc/2, fc/4, fc/8 and fc/16 (AD prescaler outputs). To achieve the guaranteed accuracy, the A/D conversion clock must be 6.75 MHz or less, that is, the A/D conversion time must be 7.85  $\mu$ s or longer.

#### 15.3.8 Storing and Reading A/D Conversion Results

A/D conversion results are stored in upper and lower A/D conversion result registers for normal A/D conversion (ADREG08H/L through ADRG7FH/L).

In fixed channel repeat conversion mode, A/D conversion results are sequentially stored in ADREG08H/L through ADREG7FH/L. If <ITM1:0> is so set as to generate the interrupt each time one A/D conversion is completed, conversion results are stored only in ADREG08H/L. If <ITM1:0> is so set as to generate the interrupt each time four A/D conversions are completed, conversion results are sequentially stored in ADREG08H/L through ADREG3BH/L.

Table 15.3.8.1 shows analog input channels and related A/D conversion result registers.

		A/D convers	sion result register			
Analog input channel	Conversion modes other than shown to the right	Fixed channel repeat conversion mode (every one conversion)	Fixed channel repeat conversion mode (every four conversions)	Fixed channel repeat conversion mode (every eight conversions)

AN22	ADREG6EH/L					
AN23	ADREG7FH/L					

Table 15.3.8.1 Analog Input Channels and Related A/D Conversion Result Registers

# 15.3.9 Data Polling

To process A/D conversion results without using interrupts, ADMOD0<EOCF> must be polled. If this flag is set, conversion results are stored in a specified A/D conversion result register. After confirming that this flag is set, read that conversion result storage register. In reading the register, make sure that you first read upper bits and then lower bits to detect an overrun. If OVRn is "0" and ADRnRF is "1" in lower bits, a correct conversion result has been obtained.

# 16. Watchdog Timer (Runaway Detection Timer)

The TMP19A64 has a built-in watchdog timer for detecting runaways.

The watchdog timer (WDT) is for detecting malfunctions (runaways) of the CPU caused by noises or other disturbances and remedying them to return the CPU to normal operation. If the timer detects a runaway, it generates a non-maskable interrupt to notify the CPU.

By connecting the output of the watchdog timer to a reset pin (inside the chip), it is possible to force the watchdog timer to reset itself.

# 16.1 Configuration

Fig. 16.1 shows the block diagram of the watchdog timer.

Fig. 16.1 Block Diagram of the Watchdog Timer

### 16.2 Watchdog Timer Interrupt

The watchdog timer consists of the binary counters that are arranged in 22 stages and work using the  $f_{SYS/2}$  system clock as an input clock. The outputs produced by these binary counters are  $2^{15}$ ,  $2^{17}$ ,  $2^{19}$  and  $2^{21}$ . By selecting one of these outputs with WDMOD <WDTP1:0>, a watchdog timer interrupt can be generated when an overflow occurs, as shown in Fig. 16.2.1.

Because the watchdog timer interrupt is a non-maskable interrupt factor, NMIFLG <WDT> at the INTC performs a task of identifying it.

When an overflow occurs, resetting the chip itself is an option to choose. If the chip is reset, a reset is effected for a 32-state time, as shown in Fig. 16.2.2. If this reset is effected, the clock  $f_{SYS}$  that the clock gear generates by dividing the clock  $f_C$  of the high-speed oscillator by 8 is used as an input clock  $f_{SYS/2}$ .

32-state (9.48  $\mu$ s @ f_C = 54 MHz, f_{sys} = 6.75 MHz, f_{sys/2} = 3.375 MHz)

Fig. 16.2.2 Reset Mode

(Note 1) When the watchdog timer functions to <u>effect</u> a reset, sampling of the status of the <u>PLLOFF</u> pin still continues. Therefore, use the <u>PLLOFF</u> pin at the level fixed to "H."

(Note 2) If the watchdog timer is operated when the high-frequency oscillator is idle, the system reset operation initiated by the watchdog timer becomes erratic due to the unstable oscillation of the high-frequency oscillator. Therefore, do not operate the watchdog timer when the high-frequency oscillator is idle.

## 16.3 Control Registers

The watchdog timer (WDT) is controlled by two control registers WDMOD and WDCR.

## 16.3.1 Watchdog Timer Mode Register (WDMOD)

① Specifying the detection time of the watchdog timer <WDTP1: 0>

This is a 2-bit register for specifying the watchdog timer interrupt time for runaway detection. When a reset is effected, this register is initialized to WDMOD <WDTP1, 0> = "00." Fig. 16.3.1.1 shows the detection time of the watchdog timer.

② Enabling/disabling the watchdog timer <WDTE>

When reset, WDMOD <WDTE> is initialized to "1" and the watchdog timer is enabled.

To disable the watchdog timer, this bit must be set to "0" and, at the same time, the disable code (B1H) must be written to the WDCR register. This dual setting is intended to minimize the probability that the watchdog timer may inadvertently be disabled if a runaway occurs.

To change the status of the watchdog timer from "disable" to "enable," set the <WDTE> bit to "1."

③ Watchdog timer out reset connection <RESCR>

This register is used to make a non-maskable interrupt (INTWDT) setting associated with the detection of a runaway or to make a connection setting after an internal reset. After a reset, WDMOD <RESCR> is initialized to "0," and a non-maskable interrupt setting is established. For information on the status of non-maskable interrupts, refer to the NMIFLG register which is described in Chapter 6 "Interrupts."

0

Fig. 16.3.1.1 Watchdog Timer Mode Register

### 16.3.2 Watchdog Timer Control Register (WDCR)

This is a register for disabling the watchdog timer function and controlling the clearing function of the binary counter.

• Disabling control

By writing the disable code (B1H) to this WDCR register after setting WDMOD <WDTE> to "0," the watchdog timer can be disabled.

WDMOD $\leftarrow$  0---Clears WDTE to "0."WDCR $\leftarrow$  1011001Writes the disable code (B1H).

• Enabling control

Set WDMOD <WDTE> to "1."

• Watchdog timer clearing control

Writing the clear code (4EH) to the WDCR register clears the binary counter and allows it to resume counting.

WDCR  $\leftarrow$  0 1 0 0 1 1 1 0 Writes the clear code (4EH).

(Note) Writing the disable code (BIH) clears the binary counter.

		7	6	5	4	3	2	1	0

Others	

Fig. 16.3.2.1 Watchdog Timer Control Register

## 16.4 Operation Description

The watchdog timer generates the INTWD interrupt after a lapse of the detection time specified by the WDMOD <WDTP1, 0> register. Before generating the INTWD interrupt, the binary counter for the watchdog timer must be cleared to "0" using software (instruction). If the CPU malfunctions (runs away) due to noise or other disturbances and cannot execute the instruction to clear the binary counter, the binary counter overflows and the INTWD interrupt is generated. The CPU is able to recognize the occurrence of a malfunction (runaway) by identifying the INTWD interrupt and to restore the faulty condition to normal by using a malfunction (runaway) countermeasure program. Additionally, it is possible to resolve the problem of a malfunction (runaway) of the CPU by connecting the watchdog timer out pin to reset pins of peripheral devices.

The watchdog timer begins operation immediately after a reset is cleared.

In STOP mode, the watchdog timer is reset and in an idle state. When the bus is open ( $\overline{BUSAK} = "L"$ ), it continues counting. In IDLE mode, its operation depends on the WDMOD <I2WDT> setting. Before putting it in IDLE mode, WDMOD <I2WDT> must be set to an appropriate setting, as required.

Examples:

1	To clear th	e bi	naı	ry	co	un	tei	:			
			7	6	5	4	3	2	1	0	
	WDCR	←	0	1	0	0	1	1	1	0	Writes the clear code (4EH)
~										_	18
(2)	To set the o	lete	cti	on	ti	me	e 0	f tl	he	watch	dog timer to $2^{18}/f_{SYS}$
			7	6	5	4	3	2	1	0	
	WDMOD	←	1	0	1	-	-	-	-	-	
3	To disable	the	wa	tcl	hd	og	; ti	me	er		
			7	6	5	4	3	2	1	0	
	WDMOD	$\leftarrow$	0	_	_	_	_	_	_	-	Clears WDTE to "0"
	WDCR	←	1	0	1	1	0	0	0	1	Writes the disable code (B1H)

Note: If the watchdog timer is operated when the high-frequency oscillator is idle, the system reset operation initiated by the watchdog timer becomes erratic due to the unstable oscillation of the high-frequency oscillator. Therefore, do not operate the watchdog timer when the high-frequency oscillator is idle.

# 17. Backup Module (Clock Timer, Backup RAM)

# 17.1 Features

The TMP19A64 has a backup module (backup mode) with a built-in timer dedicated to clock operations and a built-in backup RAM. Using this backup module, the TMP19A64 can operate in low-power-consumption operation modes. Specifically, power to all blocks (CPU, peripheral I/Os, etc.) except the backup module is disconnected; because only the backup module is supplied with power, it is possible to reduce the amount of consumption current greatly.

# 17.2 Block Diagram

Fig. 17.2 shows the block diagram of the backup module.

Fig. 17.2 Block Diagram of the Backup Module

Precautions for the use of the backup module:

- Low-speed oscillation starts when the backup module (BVCC) is powered on. The software start or stop of low-speed oscillation is not permitted.
- To put the TMP19A64 in backup mode or normal operation mode, necessary settings must be made.
- When the backup module is operating in SLOW mode, access to the backup RAM is prohibited.
- The functions that can be initialized with **BRESET** are as follows:

Clock timer: Initialize

Backup RAM: Undefined Backup module reset flag: Initialize

Registers in the backup module (RTCFLG, RTCCR, RTCREG)

Low-speed oscillator: Continued oscillation

• If the backup module and the low-frequency oscillator are not used, the following settings must be made:

Power supply level: BVCC, BRESET GND level: XT1, BUPMD

### 17.3 Backup Mode

A backup mode is provided as a system operation mode. In backup mode, the power to all blocks except the backup module is disconnected so that the TMP19A64 can operate with low power consumption.

Fig. 17.3 is the state transition diagram showing a transition to the backup mode.

Fig. 17.3 Block Diagram of the Backup Module

# 17.4 Backup Mode Operation

### 17.4.1 Transition to Backup Mode

To put the TMP19A64 into backup mode, first set the backup mode trigger pin (BUPMD) to "0," and then cut off the main power supply (DVCC3, DVCC15). When performing these two steps, caution must be used because there is the possibility that data is being written to the backup RAM. Therefore, steps must be performed according to the sequence shown below. Additionally, to recover from backup mode, the power must be turned on and signals must be processed according to the sequence shown below.

- To recover from backup mode, steps ①, ② and ③ must be performed in this order.
- If data is being written to the backup RAM in the backup module, the period (4) must be more than 50 clocks (1 µsec (@54 MHz)) in order to guarantee the integrity of data.

### 17.4.2 Power-on (Recovery from Backup Mode)

Example: If the DVCC15 power and the BVCC power are activated with different timings

- t1: As BVCC stabilizes, BRESET is maintained at "L" for more than 2 ms*. (* This time length differs depending on the characteristics of the oscillator.)
- t2: BUPMD is set to "H" after a lapse of the warming-up time for the high-speed oscillator.
- t3: RESET is cleared after the level of BUPMD changes to "H." (The backup module is initialized according to the initial routine.)

<Precautions for the transition from normal operation mode to STOP mode>

Even if the instruction to move to STOP mode has been executed, low-speed oscillation continues as long as BVCC (power supply for the backup module) is supplying power. Therefore, after the instruction to move to STOP mode is executed, BVCC must be shut down. To recover from STOP mode, first start BVCC, BRESET and BUPMD in the same sequence as they are powered on, and then clear STOP mode.

### 17.5 Backup RAM

#### 17.5.1 Features

The backup module has a built-in backup RAM (512 bytes) to be used when the TMP19A64 operates in low-power-consumption operation mode. This RAM holds data when the TMP19A64 is operating in backup mode. The data held in the RAM remains intact even if a reset is executed.

- Backup RAM area (512 bytes): 0xFFFF_E800 through 0xFFFF_E9FF
- Data in the backup RAM area is retained when the TMP19A64 is operating in backup mode.
- The data held in the backup RAM area is retained even if a reset (/RESET) is executed.
- The /BRESET pin is used to initialize (undefined value) the backup RAM area.

Note: Concerning the access to the backup RAM area for a read or write, a time length equal to 10 system clocks is required to process one such access.

## 17.6 Clock Timer

#### 17.6.1 Features

The backup module has a built-in clock timer to be used when the TMP19A64 operates in low-power consumption operation mode. This clock timer using 32.768 kHz as a low clock frequency can generate interrupts at time intervals of 0.125s, 0.250s, 0.500s and 1.000s so that the TMP19A64 is able to use the clock function when operating in low-power-consumption operation modes.

This clock timer can be operated in all operation modes of low-frequency oscillation. The interrupt generated by the clock timer allows the TMP19A64 to recover from standby mode (except STOP mode). To use the clock timer interrupt (INTRTC), the IMCGD register in the CG must be set to an appropriate setting.

Fig. 17.6.1 shows the block diagram of the clock timer.

Fig. 17.6.1 Block Diagram of the Clock Timer

## 17.6.2 Registers

The clock timer is controlled by the clock timer control register (RTCCR), backup mode flag register (RTCFLG), and clock timer count cumulative register (RTCREG). These registers are the 32-bit registers that can be initialized by /BRESET.

Fig. 17.6.2.1 shows the clock timer control register.

Fig. 17.6.2.1 Clock Timer Control Register

(Note)	To access this register, 32-bit access is required.	
(Note)	Values read from the registers are undefined until /BRESET is activated.	
(Note)	Values read from RTCCR <rtcrclr> are always "1."</rtcrclr>	
(Note)	Before changing the RTCCR <rtcssel1:0> setting, make sure that</rtcssel1:0>	
. ,	RTCCR <rtcrun> is "0" and that the RTC interrupt is disabled.</rtcrun>	

The backup mode flag register RTCFLG is a 32-bit register that has the <BUPFLG> bit for monitoring the activation of /BRESET and can be initialized by /BRESET. By writing "1" to the <BUPFLG> bit after /BRESET when starting the backup module, this register can be used as a /BRESET activation monitor. Fig. 17.6.2.2 shows the clock timer control register.

Fig. 17.6.2.2 Backup Mode Flag Register

(Note) Values read from this register are undefined until /BRESET is activated.
 (Note) For this register, 32-bit access is required.

(Note) Only "1" can be written to the <BUPFLG> bit.

(Note) After /BRESET, the <BUPFLG> bit changes to "0." Therefore, this register can be used as a /BRESET activation monitor by writing "1" after /BRESET when starting the backup module.

The clock timer is provided with a clock count cumulative register (RTCREG) for counting the number of times interrupts are generated. If 1.0s is selected as an interrupt generation cycle, a maximum of 4294967296 seconds can be retained (136 years, 70 days, 6 hours, 28 minutes, and 16 seconds).

(Note 1) X means "don't care."
 (Note 2) To disable the interrupt generated in standby mode, IMCD must be first set and then IMCGD.

# 18. Key-on Wakeup

## 18.1 Outline

- The TMP19A64 has 8 key inputs, KEY0 to KEY7, which can be used for releasing the STOP/SLEEP mode or for external interrupts. Note that interrupt processing is executed with one interrupt factor for the 8 inputs. Each key input can be configured to be used or not, by programming (KWUPSTn).
- The active state of each input can be configured to the rising edge, the falling edge, the high level or the low level, by programming (KWUPSTn).
- An interrupt request is cleared by reading the key interrupt state register KWUPST in the interrupt processing.
- The key input pins have pull-up functions, which can be enabled or disabled by programming the key pull-up control register KUPPUP.

# 18.2 Key-on Wakeup Operation

The TMP19A64 has 8 key input pins, KEY0 to KEY7. Program the IMCGC0<KWUPEN> register in the CG to determine whether to use the key inputs for releasing the STOP/SLEEP mode or for normal interrupts. Setting <KWUPEN> to "1" causes all the key inputs, KEY0 to KEY7, to be used for interrupts for releasing the STOP/SLEEP mode. Program KWUPSTn<KEYnEN> to enable or disable interrupt inputs for each key input pin. Also, program KWUPSTn<KEYn1: KEYn0> to define the active state of each key input pin to be used. Detection of key inputs is carried out in the KWUP block, and the detection results are notified to the IMCGD register in the CG as the active high level. Therefore, program IMCGD<EMCGC1:CO> to "01" to determine the detection level to the high level. The results of detection in the CG are also notified to the interrupt controller INTC as the active high level. Therefore, program the INTC to "01" to define the corresponding interrupt as the high level. Setting IMCGD<KWUPEN> to 0 (default) configures all the input pins, KEY0 to KEY7 to the normal interrupts. In this case, you don't have to make settings at the CG, but just specify the INTC detection level to the high level. Program KWUPSTn in the same way to enable or disable each key input and define their active states. Reading KWUPST during interrupt processing clears the generated key interrupt requests.

(Note) If two or more key inputs are generated, the interrupt requests, which have been generated before the sequence of clearing the interrupt requests carried out in the interrupt processing routine that corresponds to the first key input, will be cleared at the same time. Key interrupts are generated again for the interrupt requests that are generated after the said sequence of clearing the interrupt requests.

# 18.3 Pull-up Function

Each key input has the pull-up function. Pull-up can be enabled for each bit of key inputs KEY0 to KEY7 by setting KUPPUP<KEYPUP0:7> to "1." The pull-up function does not work for the key inputs that are disabled at KWUPSTn<KEYnEN>, independently of the KUPPUP<KEYPUP> setting.

#### Cautions on use of key inputs with pull-up enabled

- A) When you make the first setting after turning the power ON
  - 1) Set KUPPUP ( $\langle KEYPUPn \rangle = "1"$ ).
  - 2) Set KWUPSTn<KEYnEN> to "1" for the KEYn input to be used.
  - 3) Wait until the pull-up operation is completed.
  - 4) Set KWUPSTn to define the active state of the KEYn input to be used.
  - 5) Clear interrupt requests by reading KWUPST.
  - 6) Set CG and the INTC. (Refer to Chapter 6, "Interrupt Settings" for the details of setting methods.)
- B) To change the active state of a key input during operation
  - 1) Disable key interrupts by setting IMC3<ILD2:D0> to "000" at the INTC.
  - 2) Change the active state by setting KWUPSTn for the KEYn input to be changed.
  - 3) Clear interrupt requests by reading KWUPST.
  - 4) Enable the key interrupt at the INTC. (Set IMC3<ILD2:D0> to a desired level.)
- C) To enable a key input during operation
  - 1) Disable key interrupts by setting IMC3<ILD2:D0> to "000" at the INTC.
  - 2) Set KWUPSTn<KEYnEN> to "1" for the key input to be used.
  - 3) Wait until the pull-up operation is completed.
  - 4) Define the active state of the key input to be used at the corresponding KWUPSTn.
  - 5) Clear interrupt requests by reading KWUPST.
  - 6) Enable key interrupts at the INTC. (Set IMC3< ILD2:D0> to a desired level.)

#### Cautions on use of key inputs with pull-up disabled

- A) When you make the first setting after turning the power ON
  - 1) Set KUPPUP ( $\langle KEYPUPn \rangle = "0"$ )
  - 2) Set KWUPSTn to define the active state of the KEYn input to be used.
  - 3) Clear interrupt requests by reading KWUPST.
  - 4) Set KWUPSTn<KEYnEN> to "1" for the KEYn input to be used.
  - 5) Set CG and the INTC. (Refer to Chapter 6, "Interrupt Settings" for the details of setting methods.)
- B) To change the active state of a key input during operation
  - 1) Disable key interrupts by setting IMC3<ILD2:D0> to "000" at the INTC.
  - 2) Change the active state by setting KWUPSTn for the key input to be changed.
  - 3) Clear interrupt requests by reading KWUPST.
  - 4) Enable key interrupts at the INTC. (Set IMC3< ILD2:D0> to a desired level.)
- C) To enable a key input during operation
  - 1) Disable key interrupts by setting IMC3<ILD2:D0> to "000" at the INTC.
  - 2) Define the active state by setting KWUPSTn for the key input to be used.
  - 3) Clear interrupt requests by reading KWUPST.
  - 4) Set KWUPSTn<KEYnEN> to "1" for the key input to be used.
  - 5) Enable key interrupts at the INTC. (Set IMC3<ILD2:D0> to a desired level.)

# **18.5** Detection of Key Input Interrupts and Clearance of Requests

When KEYnEN is set to 1 and an active signal is input to KEYn, the KEYINTn channel that corresponds to KWUPST is set to "1," indicating that an interrupt is generated. The KWUPST is the read-only register. Reading this register clears the corresponding bit that has been set to "1."

If the active state is set to the high or low level, the corresponding bit of the KWUPST register remains "1" after it is read, unless the external input is withdrawn.

# **19. ROM Correction Function**

This chapter describes the ROM correction function built into the TMP19A64.

## 19.1 Features

- Using this function, eight pieces of one-word data or four pieces of eight-word data can be replaced.
- If an address (lower 5 or 2 bits are "don't care" bits) written to the address register matches an address generated by the PC or DMAC, ROM data is replaced by data generated by the ROM correction data register which is established in a RAM area assigned to the above address register.
- ROM correction is automatically authorized by writing an address to each address register.

# 19.2 Description of Operations

By setting in the address register ADDREGn a physical address (including a projection area) of the ROM area to be corrected, ROM data can be replaced by data generated by a data register in a RAM area assigned to ADDREGn. The ROM correction function is automatically enabled when an address is set in ADDREGn, and it cannot be disabled. After a reset, the ROM correction function is disabled. Therefore, to execute ROM correction with the initial setting after a reset is cleared, it is necessary to set an address in ADDREG. As an address is set in ADDREG the ROM correction function is enabled for this register. If the CPU has the bus right, ROM data is replaced when the value generated by the PC matches that of the address register. If the DMAC has the bus right, ROM data is replaced when a source or destination address generated by the DMAC matches the value of the address register. For example, if an address is set in ADDREG0 and ADDREG3, the ROM correction function is enabled for this area; match detection is performed on these registers, and data replacement is executed if there is a match. Data replacement is not executed for ADDREG1, ADDREG2, and ADDREG4 through ADDREG7. Although the bit <31:5> exists in address registers, match detection is performed on A<20:5>. Internal processing is that data replacement is executed by multiplying the ROMCS signal showing a ROM area by the result of a match detection operation performed by ROM correction circuitry. If eight-word data is replaced, an address for ROM correction can be established only on an eight-word

boundary, and data is replaced in units of 32 bytes. If only part of 32-byte data must be replaced with different data, the addresses that do not need to be replaced must be overwritten with the same data as the one existing prior to data replacement.

Register	Address	RAM area	Number of words
ADDREG0	0xFFFF_E540	0xFFFD_FF60 - 0xFFFD_FF7F	8
ADDREG1	0xFFFF_E544	0xFFFD_FF80 - 0xFFFD_FF9F	8
ADDREG2	0xFFFF_E548	0xFFFD_FFA0 - 0xFFFD_FFBF	8
ADDREG3	0xFFFF_E54C	0xFFFD_FFC0 - 0xFFFD_FFDF	8

(Note 1) Data cannot be transferred by DMA to the address register. However, data can be transferred by DMA to the RAM area where data for replacement is placed. The ROM correction function supports data replacement for both CPU and DMA access.

(Note 2) Writing back the initial value "0x00" allows data at the reset address to be replaced.

# 20. Security Function

## 20.1 General

This device is implemented with the ROM security function for the internal ROM (flash) area as well as the DSU security function to inhibit use of DSU (DSU-Probes). The following three security functions are available:

- Flash security
- ROM security
- DSU security

#### 20.2 Features

#### 20.2.1 Flash Security

The flash security function refers to the condition where all the memory areas are protected through the automatic protection bit programming function to use the FLCS <PROTECT3:0> bits inhibiting write and erase operations of the internal ROM data for individual protection areas (in 512 kB blocks). In this case, the flash memory cannot be read from any area outside the flash memory such as the internal RAM areas where the protection bit erase command cannot be accepted. After this, no command writing can be performed normally. The flash security function is also a function to be necessary in enabling the ROM security and DSU security functions.

When the automatic protection bit erase command is executed while the system is in a secure condition, the flash memory is automatically initialized within the device. Therefore, be sufficiently careful in making a transition to a secure state.

## 20.2.2 ROM Security

The ROM security function can inhibit data write/read operations to/from the internal ROM. This function is used together with the flash security function.

Although the PC of RAM area instructions that have been replaced from the ROM area through the ROM correction function indicates an address in the flash ROM area, it is actually in the RAM area and thus data cannot be read in the condition ROM security is in place. For reading data using an instruction in the RAM area that has been replaced from the ROM area, some special method such as to use a program in the ROM area to write the data value into RAM will be necessary.

When the ROM security is applied to the ROM area, the following operations are inhibited:

- Operation to load or store ROM area data using an instruction placed outside the ROM area
- DMAC data transfer of ROM area data
- EJTAG based operation to load or store ROM area data
- Boot ROM operation to load or store ROM area data
- Flash writer operation to load or store ROM area data
- Access to security related registers (ROMSEC1 and ROMSEC2) in the ROM area using an instruction placed outside the ROM area.
- Execution of any flash command sequence other than the automatic block protection clear command and automatic block security clear command in the writer mode and any flash command sequence in the single mode or boot mode that specifies an address in the ROM area

Even when the ROM security is applied to the ROM area, the following operations can be performed:

- Loading of ROM area data using an instruction placed in the ROM area
- Loading of data outside the ROM area to use an instruction placed in any area
- Branch instruction to jump to the ROM area to use an instruction placed in any area
- PC trace (with some limitations) and break operations in the ROM area to use EJTAG

#### 20.2.3 DSU Security

The DSU security function prevents easy reading of the internal flash memory by a third party other than the authorized user when an onboard DSU probe is used. By enabling the DSU security function, it becomes impossible to read the internal flash memory from a DSU probe. This function is used together with the flash security function.

# 20.3 Outline Security Configuration and Correspondence Table

Fig. 21.3.1 Various Security Conditions (Outline)

			on moue			
	Protection bit setting, FLCS <protect3:0></protect3:0>		11	11		≠1111

	Generation of command other than protection bit erase command	× *7	× *7	× *7	× *7	Δ *9

Table 21.3.1 Various Security Conditions in Each Mode

*1 : Always reads "0x00000098."

*2 : Masks the stored data (Register cannot be written or cleared.)

*3 : Masks the stored data (Register cannot be written or cleared.)

*4 : Command address is masked and the flash memory cannot recognize the command.

*5 : Command address is masked and the flash memory cannot recognize the command.

*6 : Bus error exceptions are generated. (When set to DMAC register.)

*7 : Commands are not recognized because of the flash security state.

*8 : Commands result in flash area erase and protection bit erase operations because of the flash security state.

*9 : Command conversion is performed in the flash interface according to the protection bit status and input command.

#### 20.4 Register

#### Flash control/ status register

This resister is used to monitor the status of the flash memory and to indicate the block protection status.

#### Table 21.3.2 Flash Control Register

This bit is read after reset to identify whether the ROM is a flash ROM or a mask ROM.

Flash ROM: "0" Mask ROM: "1"

Bits [7:4]: Protection bits (x: can be set to any combination of areas)

Each of the protection bits (4 bits) represents the protection status of the corresponding area. When a bit is set to "1," it indicates that the area corresponding to the bit is protected. When the area is protected, data cannot be written into it.

(Note) This register must be 32-bit accessed.

(Note) This register is a write-only register. Any value read is undefined.

#### 20.5 Setting Security Configuration

If it is necessary to rewrite the flash memory or protection bits while the device is in a secure state, either perform the automatic protection bit erase operation or clear the ROM security function. While the DSU security is applied, any DSU cannot be used.

The setting is necessary to make DSU-probe available beforehand if an automatic protection bit programming is executed to result in a flash security state.

When the automatic protection bit erase command is executed while the system is in the flash security mode, the flash memory is automatically initialized within the device. Therefore, be sufficiently careful in making a transition to a secure state.

#### 20.5.1 Flash Security

Setting or clearing of flash security is made using a command sequence to the flash memory to use the protection bit programming command. Refer to command sequence descriptions in the section describing flash memory operation for more details.

#### 20.5.2 ROM Security

In order to prevent the ROM security function from being accidentally removed by system runaway, etc., a double action method is used to set or clear the ROM security function. To make ROM security functional, first set the ROM security register ROMSEC1 <RSECON> to "1" and then write the security code "0x0000_003D" to the ROM security lock register ROMSEC2. Similarly, when the ROM security function is to be cleared, first set the ROM security register ROMSEC1 <RSECON> to "0" and then write the security code "0x0000_003D" to the ROM security register ROMSEC1 <RSECON> to "0" and then write the security code "0x0000_003D" to the ROM security lock register ROMSEC1 <RSECON> to "0" and then write the security code "0x0000_003D" to the ROM security lock register ROMSEC1 <RSECON> to "0" and then write the security code "0x0000_003D" to the ROM security lock register ROMSEC1.

(Note) The ROM security register has a power on reset circuit and the <RSECON> bit is set to "1" after power is turned on. If the flash security function is in place at this point, the ROM security function is automatically enabled to inhibit data write/read operations to/from the internal ROM.

#### 20.5.3 DSU Security

DSU enable/disable (Enables or disables use of DSU probes for debugging)

In order to prevent the DSU inhibit function from being accidentally removed by system runaway, etc., a double action method is used to clear the DSU inhibit function. So, first set the DSU security mode register DSUSEC1 <DSUOFF> to "0" and then write the security code "0x0000_00C5" to the DSU security control register DSUSEC2. Then, debugging to use a DSU probe is allowed. While power to the device is still applied, setting DSUSEC1 <DSUOFF> to "1" and writing "0x0000_00C5" to the DSUSEC2 register will enable the security function again.

(Note) The DSU security mode register has a power on reset circuit and the <DSUOFF> bit is set to "1" after power is turned on. If the flash security function is in place at this point, the DSU security function is automatically enabled and it becomes impossible to read the internal flash memory from any DSU probe.

#### 20.5.4 ROM Security Register: ROMSEC1 <RSECON>

The ROM security register is provided with a power on reset circuit. Note that the data to be read from the ROMSEC1 <RSECON> bit is different from the original data written to the register. The outline schematic diagram is shown below:

# 20.5.5 DSU Security Mode Register: DSUSEC1 <DSUOFF>

The DSU security mode register is provided with a power on reset circuit.

Note that the data to be read from the DSUSEC1 <DSUOFF> bit is different from the original data written to the register. The outline schematic diagram is shown below:

# 21. Table of Special Function Registers

Special function registers are allocated to an 8K-byte address space from FFFFE000H to FFFFFFFH.

- [1] Port registers
- [2] Watchdog timer
- [3] 16-bit timer
- [4] I²CBUS/serial channel
- [5] UART/serial channel
- [6] 10-bit A/D converter
- [7] Key-on wake-up
- [8] 32-bit input capture
- [9] 32-bit compare
- [10] Interrupt controller
- [11] DMA controller
- [12] Chip select/wait controller
- [13] Access control
- [14] Security control
- [15] FLASH control
- [16] ROM correction
- [17] Clock timer
- [18] Clock generator
- (Note) 0xFFFF_F000 to 0xFFFF_FFFF are a little-endian area. 0xFFFF_E000 to 0xFFFF_EFFF are a bi-endian area.
- (Note) For continuous 8-bit long registers, 16- or 32-bit access is possible. The use of 16- or 32-bit access requires that an even-number address be accessed and that an even-number address does not contain undefined areas.

# TMP19A64(rev1.1)-21-19

# 22. Electrical Characteristics

The letter x in equations presented in this chapter represents the cycle period of the fsys clock selected through the programming of the SYSCR1.SYSCK bit. The fsys clock may be derived from either the high-speed or low-speed crystal oscillator. The programming of the clock gear function also affects the fsys frequency. All relevant values in this chapter are calculated with the high-speed (fc) system clock (SYSCR1.SYSCK = 0) and a clock gear factor of 1/fc (SYSCR1.GEAR[2:0] = 000).

#### 22.1 Absolute Maximum Ratings

Parameter		Symbol	Rating	Unit
			– 0.3 to 3.0	
Currente unaltan	_	Vcc3 (I/O)	- 0.3 to 3.9	
Supply voltag	le	AVCC (A/D)	– 0.3 to 3.9	V
		BVCC	– 0.3 to 3.9	
Supply voltage	e	V _{IN}	$-$ 0.3 to $V_{\text{CC}}\text{+}0.3$	V
Low-level	Per pin	I _{OL}	5	
output current	Total	$\Sigma I_{OL}$	50	mA
High-level	Per pin	I _{ОН}	-5	IIIA
output current	Total	$\Sigma I_{OH}$	50	
Power dissipa	ation (Ta = 85°C)	PD	600	mW
Soldering ten	nperature (10 s)	T _{SOLDER}	260	°C
Storage temperature		T _{STG}	-40 to 125	°C
Operating	Except during flash W/E	T _{OPR}	-20 to 85	°C
temperature	During flash W/E		0 to 70	
Write/erase c	ycles	N _{EW}	100	cycle

 $V_{CC15}$ =DVCC15=CVCC15=FVCC15,  $V_{CC}$ 3=DVCC3n (n=0 to 4), AVCC=AVCC3m (m=1 to 2)  $V_{SS}$ =DVSS * =AVSS * =CVSS=FVSS

Note: The Absolute Maximum Rating is a rating that must never be exceeded, even for an instant. Not a single Absolute Maximum Rating value can be exceeded. If any Absolute Maximum Rating value is exceeded, the product may be damaged or weakened, or damage or combustion may cause personal injury. Always be sure to design your application devices so the Absolute Maximum Rating is never exceeded.

#### 22.7 Transfer with DMA Request

The following shows an example of a transfer between the on-chip RAM and an external device in multiplex bus mode.

- 16-bit data bus width, non-recovery time
- Level data transfer mode
- Transfer size of 16 bits, device port size (DPS) of 16 bits
- Source/destination: on-chip RAM/external device

The following shows transfer operation timing of the on-chip RAM to an external bus during write operation (memory-to-memory transfer).

(1) Indicates the condition under which Nth transfer is performed successfully.

(2) Indicates the condition under which (N + 1)th transfer is not performed.

			(1)Min	(2)Max	Min	Max	
2	RD asserted to DREQn negated (external device to on-chip RAM transfer)	tDREQ_r	(W+1)x	(2W+ALE+8)x -51	37	152.5	ns
3	WR / HWR rising to DREQn negated (on-chip RAM to external device transfer)	tDREQ_w	-(W+2)x	(5+WAIT)x-51.8	-55.5	59.2	ns

# (2) DVCC15=CVCC15=FVCC15=1.35V to 1.65V, AVCC3m =FVCC3=2.7V to 3.3V

No.	Parameter	Symbol	Equ	54 MHz	Unit		
			(1)Min	(2)Max	Min	Max	
2	RD asserted to DREQn negated (external device to on-chip RAM transfer)	tDREQ_r	(W+1) x	(2W+ALE+8) x-56	37	147.5	ns
3	WR / HWR rising to DREQn negated (on-chip RAM to external device transfer)	tDREQ_w	-(W+2)x	(5+WAIT)x-56.8	-55.5	54.2	ns

### DVCC33=1.65V to 1.95V, DVCC30/31/32/34=1.65V to 3.3V, Ta=-20 to 85°C (m=1 to 2)

- W: Number of wait-state cycles inserted. In the case of (2 + N) externally generated wait states with N = 1, W becomes 4
- ALE: Apply ALE = ALE 1 clock, ALE = 1 for ALE 2 clock. The values in the above table are obtained with W = 1, ALE = 1.

### 22.8 Serial Channel Timing

(1) I/O Interface mode (DVCC3n = 1.65V to 3.3V)

In the table below, the letter x represents the fsys cycle period, which varies depending on the programming of the clock gear function.

#### (1) SCLK input mode (SIO0 to SIO6)

Parameter	Symbol	Equation	54	Unit		
	Symbol	Min	Max	Min	Max	UIIIL
SCLK period	t _{SCY}	12x		222		ns
SCLK Clock High width(input)	TscH	6x		111		ns
SCLK Clock Low width (input)	TscL	6x		111		ns
TxD data to SCLK rise or fall*	t _{OSS}	2x-30		6		ns
TxD data hold after SCLK rise or fall*	t _{OHS}	8x-15		129		ns
RxD data valid to SCLK rise or fall*	t _{SRD}	30		30		ns
RxD data hold after SCLK rise or fall*	t _{HSR}	2x+30		66		ns

* SCLK rise or fall: Measured relative to the programmed active edge of SCLK.

#### 2. SCLK output mode (SIO0 to SIO6)

Parameter	Symbol	Equation		54	Unit	
r ar anic Lei	Symbol	Min	Max	Min	Max	UIIIL
SCLK period	t _{SCY}	8x		222		ns
TxD data to SCLK rise or fall*	t _{OSS}	4x-10		62		ns
TxD data hold after SCLK rise or fall*	t _{OHS}	4x-10		62		ns
RxD data valid to SCLK rise or fall*	t _{SRD}	45		45		ns
RxD data hold after SCLK rise or fall*	t _{HSR}	0		0		ns

### 22.9 SBI Timing

(1) I2C mode

In the table below, the letters x represent the fsys periods, respectively.

n denotes the value of n programmed into the SCK (SCL output frequency select) field in the SBI0CR1.

Parameter	Symbol	Equation		Standard mode		Fast mode		Unit
Faralleter	JUDUI	Min	Max	Min	Max	Min	Max	Unit
SCL clock frequency	t _{SC∟}	0		0	100	0	400	kHz
Hold time for START condition	t _{HD:STA}			4.0		0. 6		μs
SCL clock low width (Input) (Note 1)	t _{LOW}			4. 7		1.3		μs
SCL clock high width (Output) (Note 2)	t _{HIGH}			4.0		0. 6		μs
Setup time for a repeated START condition	t _{SU;STA}	(Note 5)		4. 7		0. 6		μs
Data hold time (Input) (Note 3, 4)	t _{HD:DAT}			0.0		0.0		μs
Data setup time	t _{su:DAT}			250		100		ns
Setup time for STOP condition	t _{SU:STO}			4.0		0. 6		μs
Bus free time between STOP and START conditions	t _{BUF}	(Note 5)		4.7		1.3		μs

Note 1: SCL clock low width (output) is calculated with: (2ⁿ⁻¹+58)/(fsys/2)

Note 2: SCL clock high width (output) is calculated with (2ⁿ⁻¹+12)/(fsys/2)

Notice: On I²C-bus specification, Maximum Speed of Standard mode is 100KHz ,Fast mode is 400Khz. Internal SCL clock Frequency setting should be shown above Note1 & Note2.

Note 3: The output data hold time is equal to 12x

Note 4: The Philips I²C-bus specification states that a device must internally provide a hold time of at least 300 ns for the SDA signal to bridge the undefined region of the fall edge of SCL. However, the 19A64 SBI does not satisfy this requirement. Also, the output buffer for SCL does not incorporate slope control of the falling edges; therefore, the equipment manufacturer should design so that the input data hold time shown in the table is satisfied, including tr/tf of the SCL and SDA lines.

Software-dependent

### (2) Clock-Synchronous 8-Bit SIO mode

In the tables below, the letters x represent the fsys cycle periods, respectively. The letter n denotes the value of n programmed into the SCK (SCL output frequency select) field in the SBI0CR1.

The electrical specifications below are for an SCK signal with a 50% duty cycle. ③ SCK Input mode

Parameter	Symbol	Equation	54	Unit		
	Symbol	Min	Max	Min	Max	UIIIL
SCK period	t _{SCY}	16x		296		ns
SO data to SCK rise	t _{OSS}	$(t_{SCY}/2) - (6x + 30)$		7		ns
SO data hold after SCK rise	t _{OHS}	$(t_{SCY}/2) + 4x$		222		ns
SI data valid to SCK rise	t _{SRD}	0		0		ns
SI data hold after SCK rise	t _{HSR}	4x + 10		84		ns

### ④ SCK Output mode

Parameter	Symbol	Equation	54	Unit		
r at anic Let	Symbol	Min	Max	Min	Max	UIIIL
SCK period (programmable)	t _{SCY}	16x		296		ns
SO data to SCK rise	t _{OSS}	$(t_{SCY}^{}/2) - 20$		128		ns
SO data hold after SCK rise	t _{OHS}	$(t_{SCY}^{}/2) - 20$		128		ns
SI data valid to SCK rise	t _{SRD}	2x + 30		67		ns
SI data hold after SCK rise	t _{HSR}	0		0		ns

### 22.10 Event Counter

In the table below, the letter x represents the fsys cycle period.

Parameter	Symbol	Equa	tion	54	MHz	Unit
	Symbol	Min	Max	Min	Max	UIIIL
Clock low pulse width	t _{VCKL}	2X + 100		137		ns
Clock high pulse width	t _{VCKH}	2X + 100		137		ns

### 22.11 Timer Capture

In the table below, the letter x represents the fsys cycle period.

Parameter	Symbol	Equa	tion	54	MHz	Unit
rarameter	Symbol	Min	Max	Min	Max	UIIIL
Low pulse width	t _{CPL}	2X + 100		137		ns
High pulse width	t _{CPH}	2X + 100		137		ns

### 22.12 General Interrupts

In the table below, the letter x represents the fsys cycle period.

Parameter	Symbol	Equa	tion	54	MHz	Unit
	JUDUI	Min	Max	Min	Max	UIIIL
Low pulse width for INT0-INTA	t _{INTAL}	X + 100		118.5		ns
High pulse width for INT0-INTA	t _{INTAH}	X + 100		118.5		ns

### 22.13 NMI and STOP /SLEEP Wake-up Interrupts

Parameter	Symbol	Equa	tion	54	MHz	Unit
rarameter	Symbol	Min	Max	Min	Max	UIIIL
Low pulse width for MI and INT0-INT4	t _{INTBL}	100		100		ns
High pulse width for INT0-INT4	t _{INTBH}	100		100		ns

#### 22.14 SCOUT Pin

Parameter	Symbol	Equa	tion	54	MHz	Unit
r al ameter	Symbol	Min	Max	Min	Max	UIIIL
Clock high pulse width	t _{SCH}	0.5T – 5		4. 25		ns
Clock low pulse width	t _{SCL}	0.5T – 5		4. 25		ns

Note: In the above table, the letter T represents the cycle period of the SCOUT output clock.

#### 22.15 Bus Request and Bus Acknowledge Signals

Parameter	Symbol	Equa	tion	54	MHz	Unit
Faralleter	Symbol	Min	Max	Min	Max	UIIIL
Bus float to BUSAK asserted	t _{ABA}	0	80	0	80	ns
Bus float after BUSAK negated	t _{BAA}	0	80	0	80	ns

- Note 1: If the current bus cycle has not terminated due to wait-state insertion, the TMP19A64F20BXBG does not respond to BUSRQ until the wait state ends.
- Note 2: This broken line indicates that output buffers are disabled, not that the signals are at indeterminate states. The pin holds the last logic value present at that pin before the bus is relinquished. This is dynamically accomplished through external load capacitances. The equipment manufacturer may maintain the bus at a predefined state by means of off-chip restores, but he or she should design, considering the time (determined by the CR constant) it takes for a signal to reach a desired state. The on-chip, integrated programmable pullup/pulldown resistors remain active, depending on internal signal states.

## 22.16 KWUP Input

	1 ui	1 0	tion		MHz	
Parameter	Symbol	Min	Max	Min	Max	Unit
Low pulse width for KEY0-D	tky _{TBL}	X+100		118		ns
High pulse width for KEY0-D	tky _{TBH}	X+100		118		ns

## Pull-up Register Active

### 22.17 Dual Pulse Input

Parameter	Symbol	Equa	tion	54	MHz	Unit
	Symbol	Min	Max	Min	Max	UIIL
Dual input pulse period	Tdcyc	8Y		296		ns
Dual input pulse setup	Tabs	Y+20		57		ns
Dual input pulse hold	Tabh	Y+20		57		ns

Y: Sampling clock (fsys/2)

# 23. Notations, Precautions and Restrictions

### 23.1 Notations and Terms

- (1) I/O register fields are often referred to as <*register_mnemonic*>.<*field_name*> for the interest of brevity. For example, TRUN.TORUN means the TORUN bit in the TRUN register.
- (2) fc, fsys, state
  - fose: Clock supplied from the X1 and X2 pins
  - fpll: Clock generated by the on-chip PLL
  - fc: Clock selected by the PLLOFF pin
  - fgear: Clock selected by the SYSCR1.GEAR[1:0] bits
  - fsys: Clock selected by the SYSCR1.SYSCK bit

The fsys cycle is referred to as a state.

In addition, the clock selected by the SYSCR1.FPSEL bit and the prescaler clock source selected by the SYSCR0.PRCK[1:0] bits are referred to as fperiph and  $\phi$ T0 respectively.

### 23.2 Precautions and Restrictions

(1) Processor Revision Identifier

The Process Revision Identifier (PRId) register in the TX19A core of the TMP19A64C1D contains 0x0000_2CA1.

(2) BW0-BW1 Pins

The BW0 and BW1 pins must be connected to the DVCC2 pin to ensure that their signal levels do not fluctuate during chip operation.

(3) Oscillator Warm-Up Counter

If an external crystal is utilized, an interrupt signal programmed to bring the TMP1940CYAF out of STOP mode triggers the on-chip warm-up counter. The system clock is not supplied to the on-chip logic until the warm-up counter expires.

(4) Programmable Pullup Resistors

When port pins are configured as input ports, the integrated pull-up resistors can be enabled and disabled under software control. The pull-up resistors are not programmable when port pins are configured as output ports.

The relevant port registers are programmed with the data resister.

(5) External Bus Mastership

The pin states while the bus is granted to an external device are described in Chapter 7, I/O Ports.

(6) Watchdog Timer (WDT)

Upon reset, the WDT is enabled. If the watchdog timer function is not required, it must be disabled after reset. When relevant pins are configured as bus arbitration signals, the I/O peripherals including the WDT can operate during external bus mastership.

(7) A/D Converter (ADC)

The ladder resistor network between the VREFH and VREFL pins can be disconnected under software control. This helps to reduce power dissipation, for example, in STOP mode.

(8) Undefined Bits in I/O Registers

Undefined I/O register bits are read as undefined states. Therefore, software must be coded without relying on the states of any undefined bits.

(9) Electrostatic Discharge (ESD) Sensitivity

The following shows ESD sensitivity. Protect the device from static damage during device development or production stage. For a detailed description on ESD, see General Safety Precautions and Usage Considerations.

#### • TMP19A64C1DXBG

Specification	Sensitivity
Machine Model: MM	±200 V
Human Body Model: HBM	-1750V ~+2000 V

#### • TMP19A64F20AXBG

Specification	Sensitivity
Machine Model: MM	±200 V
Human Body Model: HBM	$-2000V \sim +2000 V$

(10) Bus Access of Debug Mode (Mask product only)

Bus Accessing is abnormal for external function with SREQ mode in Debug mode,

Which means Debug<DM>="1" in CP0 register. Of Mask Type MCU, TMP19A64C1DXBG.

Pls don't access to external function with SREQ Mode in debug mode.

(11) Notations, Precautions and Restrictions

### **Overflow Exception**

#### **Problem:**

If an overflow exception caused a jump to the exception handler and the first instruction in that exception handler caused another exception, the EPC register should point to the address of the first instruction in the exception handler. However, the EPC register might contain the address that caused the overflow exception.

#### • Problem-Causing Situation:

When, with the instruction pipeline full, an overflow exception was taken at the following sequence of instructions and then the first instruction in the overflow exception handler causes another exception

ADD, ADDI or SUB <= # Instruction that causes an overflow Jump or branch instruction <= # Instruction with a delay slot Delay slot

Note: Toshiba's compiler uses no instructions that could cause an overflow. Therefore, this problem does not occur.

#### Workaround:

Don't place a jump or branch instruction immediately following an instruction that could cause an overflow (ADD, ADDI or SUB).

#### LWL and LWR Instructions

#### Problem:

The LWL or LWR instruction might provide incorrect results.

#### • Problem-Causing Situation #1:

- a. The destination of a load instruction (LB, LBU, LH, LHU, LW, LWL or LWR) is identical to that of the LWL or LWR instruction.
- b. The instruction pipeline is full. (The load instruction and the LWL or LWR instruction will be executed consecutively.)
- c. The DMAC is programmed for data cache snooping. Once the load instruction is executed, the DMAC initiates a DMA transaction. After it has been serviced, the LWL or LWR instruction is executed.

This problem occurs when all of these conditions are true.

#### • Problem-Causing Situation #2:

- a. The destination of a load instruction (LB, LBU, LH, LHU, LW, LWL or LWR) is identical to that of the LWL or LWR instruction.
- b. The Doze or Halt bit in the Config register is set to 1 immediately before the load instruction.
- c. The instruction pipeline is full. (The load instruction and the LWL or LWR instruction will be executed consecutively.)
- d. After the load instruction is executed, the processor is put in the STOP, SLEEP or IDLE mode.
- e. After an interrupt signaling brings the processor out of the STOP, SLEEP or IDLE mode, the LWL or LWR instruction is executed.
- Note: This applies to the case in which an interrupt signaling does not generate an interrupt upon exit from STOP or IDLE mode. In other words, either the IEc bit in the Status register is cleared (interrupts disabled), or if the IEc bit is set, the priority level of the incoming interrupt signaling is lower than the mask level programmed in the CMask field in the Status register. (Exit from STOP, SLEEP or IDLE mode can be accomplished even with such settings.)

This problem occurs when all of these conditions are true.

#### Workarounds:

To use the LWL or LWR instruction,

- 1) Place a NOP between a load instruction and the LWL or LWR instruction, or
- Disable the data cache snooping of the DMAC before the LWL or LWR instruction is executed.
   Also, do not put the processor in STOP, SLEEP or IDLE mode before the LWL or LWR instruction is executed.

#### Overflow Exception When a DSU Probe Is Used

#### Problem:

It looks as if an overflow exception caused a jump to the reset and nonmaskable exception vector address (0xBFC0_0000).

#### • Problem-Causing Situation:

When an overflow exception occurs, with the processor connected to a DSU probe

Note: Toshiba's compiler uses no instructions that could cause an overflow. Therefore, this problem does not occur.

#### Workaround:

Don't place a jump or branch instruction immediately following an instruction that could cause an overflow (ADD, ADDI or SUB).

#### Malfunction of using BUSREQ signl in External Bus Access mode

#### [Condition]

- 1. In External Bus mode, using Auto WAIT insert function (as same as +N wait)
- 2. Use External Bus request signal Function (BUSREQ).
- 3. For each target product, Bus setting mode (Multiplex/ separate)、 ALE width(short/long)
- . Please refer to following table.

(Exp: ALE Band =1.5CLK, Auto wait = 3)
