# 查询HT48E70供应商 HOLTEK //O Type 8-Bit MTP MCU With EEPROM

# Features

- Operating voltage: f<sub>SYS</sub>=4MHz: 2.2V~5.5V f<sub>SYS</sub>=8MHz: 3.3V~5.5V
- Low voltage reset function
- 56 bidirectional I/O lines (max.)
- 1 interrupt input shared with an I/O line
- 2×16-bit programmable timer/event counter with overflow interrupt
- On-chip crystal and RC oscillator
- Watchdog Timer
- 1,000 erase/write cycles MTP program memory
- 8192×16 program memory ROM (MTP)
- 256×8 data memory EEPROM
- 224×8 data memory RAM

# **General Description**

The HT48E70 is an 8-bit high performance, RISC architecture microcontroller device specifically designed for multiple I/O control product applications.

The advantages of low power consumption, I/O flexibility, timer functions, oscillator options, HALT and

- HALT function and wake-up feature reduce power consumption
- 16-level subroutine nesting
- Up to  $0.5\mu s$  instruction cycle with 8MHz system clock at  $V_{DD}$ =5V
- Bit manipulation instruction
- 16-bit table read instruction
- 63 powerful instructions
- 10<sup>6</sup> erase/write cycles EEPROM data memory
- EEPROM data retention > 10 years
- All instructions in one or two machine cycles
- In system programming (ISP)
- 48-pin SSOP, 64-pin QFP package

wake-up functions, watchdog timer, buzzer driver, as well as low cost, enhance the versatility of these devices to suit a wide range of application possibilities such as industrial control, consumer products, subsystem controllers, etc.

### **Pad Assignment**

\* The IC substrate should be connected to VSS in the PCB layout artwork.

# **Pad Description**

| Pad Name                    | I/O    | Options   | Description   |
|-----------------------------|--------|---|---|
| PA0~PA7                     | I/O    | Wake-up<br>Pull-high*<br>CMOS or Schmitt<br>Input | Bidirectional 8-bit input/output port.<br>Each bit can be configured as a wake-up input by options. Software instruc-<br>tions determine if the pin is a CMOS output or Schmitt trigger input or CMOS<br>input with or without pull-high resistor (by options).   |
| PB0/BZ<br>PB1/BZ<br>PB2~PB7 | I/O    | Pull-high*<br>PB0 or BZ<br>PB1 or BZ              | Bidirectional 8-bit input/output port.<br>Software instructions determine if the pin is a CMOS output or Schmitt trigger<br>input with pull-high resistor (determined by pull-high options).<br>The PB0 and PB1 are pin-shared with BZ and BZ respectively. Once the PB0<br>or PB1 is selected as buzzer driving output, the output signals come from an<br>internal PFD generator (shared with timer/event counter). |
| VSS                         |        |   | Negative power supply, ground   |
| INT                         | I      |   | External interrupt Schmitt trigger without pull-high resistor.<br>Edge trigger is activated during high to low transition.  |
| TMR0                        | Ι      |   | Schmitt trigger input for Timer/Event Counter 0   |
| TMR1                        | Ι      |   | Schmitt trigger input for Timer/Event Counter 1   |
| PC0~PC7                     | I/O    | Pull-high*  | Bidirectional 8-bit input/output port.<br>Software instructions determine the CMOS output or Schmitt trigger input<br>(pull-high depends on options).   |
| RES                         | I      |   | Schmitt trigger reset input, active low.  |
| VDD                         |        |   | Positive power supply   |
| OSC1<br>OSC2                | І<br>О | Crystal<br>or RC                                  | OSC1 and OSC2 are connected to an RC network. For RC operation, OSC2 is an output terminal for 1/4 system clock.  |
| PD0~PD7                     | I/O    | Pull-high*  | Bidirectional 8-bit input/output port.<br>Software instructions determine if the pin is a CMOS output or Schmitt trigger<br>input (pull-high depends on options).   |
| PE0~PE7                     | I/O    | Pull-high*  | Bidirectional 8-bit input/output port.<br>Software instructions determine if the pin is a CMOS output or Schmitt trigger<br>input (pull-high depends on options).   |
| PF0~PF7                     | I/O    | Pull-high*  | Bidirectional 8-bit input/output port.<br>Software instructions determine if the pin is a CMOS output or Schmitt trigger<br>input (pull-high depends on options).   |
| PG0~PG7                     | I/O    | Pull-high*  | Bidirectional 8-bit input/output port.<br>Software instructions determine if the pin is a CMOS output or Schmitt trigger<br>input (pull-high depends on options).   |

Note: \* The pull-high resistors of each I/O port (PA, PB, PC, PD, PE, PF, PG) are controlled by options. CMOS or Schmitt trigger option of port A is controlled by an option.

# **Absolute Maximum Ratings**

| Supply VoltageV_SS-0.3V to V_SS+6.0V | Storage Temperature50°C to 125°C  |
|--------------------------------------|-----------------------------------|
| Input VoltageV_SS=0.3V to V_DD+0.3V  | Operating Temperature40°C to 85°C |

Note: These are stress ratings only. Stresses exceeding the range specified under "Absolute Maximum Ratings" may cause substantial damage to the device. Functional operation of this device at other conditions beyond those listed in the specification is not implied and prolonged exposure to extreme conditions may affect device reliability.

# **Functional Description**

#### **Execution Flow**

The HT48E70 system clock is derived from either a crystal or an RC oscillator and is internally divided into four non-overlapping clocks. One instruction cycle consists of four system clock cycles.

Instruction fetching and execution are pipelined in such a way that a fetch takes an instruction cycle while decoding and execution takes the next instruction cycle. The pipelining scheme ensures that each instructions are effectively executed in one cycle. Exceptions to this are instructions that change the contents of the program counter, such as subroutine calls or jumps, in which case, two cycles are required to complete the instruction.

#### Program Counter – PC

The program counter (PC) controls the sequence in which the instructions stored in the program ROM are executed and its contents specify a full range of program memory.

After accessing a program memory word to fetch an in-

struction code, the contents of the program counter are incremented by one. The program counter then points to the memory word containing the next instruction code.

When executing a jump instruction, conditional skip execution, loading PCL register, subroutine call or return from subroutine, initial reset, internal interrupt, external interrupt or return from interrupts, the PC manages program transfer by loading the address corresponding to each instruction.

The conditional skip is activated by instructions. Once the condition is met, the next instruction, fetched during the current instruction execution, is discarded and a dummy cycle replaces it to get the proper instruction. Otherwise proceed to the next instruction.

The lower byte of the program counter (PCL) is a readable and writeable register (06H). Moving data into the PCL performs a short jump. The destination will be within the current program ROM page.

When a control transfer takes place, an additional dummy cycle is required.

**Execution Flow** 

| Mode                           |     | Program Counter |     |    |    |        |       |         |    |    |    |    |    |

#### In System Programming

In system programming allows programming and reprogramming of HT48EXX microcontroller on application circuit board, this will save time and money, both during development in the lab. Using a simple 3-wire interface, the ISP communicates serially with the HT48EXX microcontroller, reprogramming program memory and EEPROM data memory on the chip.

| Pin Name | Function | Description              |
|----------|----------|--------------------------|
| PA0      | SDATA    | Serial data input/output |
| PA4      | SCLK     | Serial clock input       |
| RES      | RESET    | Device reset             |
| VDD      | VDD      | Power supply             |
| VSS      | VSS      | Ground                   |

ISP Pin Assignments

#### **Program Memory – ROM**

The program memory is used to store the program instructions which are to be executed. It also contains data, table, and interrupt entries, and is organized into 8192×16 bits, addressed by the program counter and table pointer.

Certain locations in the program memory are reserved for special usage:

Location 000H

This area is reserved for program initialization. After chip reset, the program always begins execution at location 000H.

Location 004H

This area is reserved for the external interrupt service program. If the  $\overline{\text{INT}}$  interrupt pin is activated, the interrupt enabled and the stack is not full, the program begins execution at location 004H.

Location 008H

This area is reserved for the Timer/Event Counter 0 interrupt service program. If a timer interrupt results from a Timer/Event Counter 0 overflow, and if the interrupt is enabled and the stack is not full, the program begins execution at location 008H.

Location 00CH

This location is reserved for the Timer/Event Counter 1 interrupt service program. If a timer interrupt results

**Program Memory** 

from a Timer/Event Counter 1 overflow, and the interrupt is enabled and the stack is not full, the program begins execution at location 00CH.

Table location

Any location in the program memory can be used as look-up tables where programmers can store fixed data. The instructions "TABRDC [m]" (the current page, one page=256 words) and "TABRDL [m]" (the last page) transfer the contents of the lower-order byte to the specified data memory, and the higher-order byte to TBLH (08H). The Table Higher-order byte register (TBLH) is read only. The table pointer (TBLP) is a read/write register (07H), which indicates the table location. Before accessing the table, the location must be placed in the TBLP. The TBLH is read only and cannot be restored. If the main routine and the ISR (Interrupt Service Routine) both employ the table read instruction, the contents of the TBLH in the main routine are likely to be changed by the table read instruction used in the ISR. Errors can occur. In other words, using the table read instruction in the main routine and the ISR simultaneously should be avoided. However, if the table read instruction has to be applied in both the main routine and the ISR, the interrupt is supposed to be disabled prior to the table read instruction. It will not be enabled until the TBLH has been backed up. All table related instructions require two cycles to

| Instruction |     |     |     |    |    | Tab | le Loca | tion |    |    |    |    |    |
|-------------|-----|-----|-----|----|----|-----|---------|------|----|----|----|----|----|
| instruction | *12 | *11 | *10 | *9 | *8 | *7  | *6      | *5   | *4 | *3 | *2 | *1 | *0 |

| TABRDL [m]  | 1   | 1   | 1   | 1  | 1  | @7  | @6      | @5   | @4 | @3 | @2 | @1 | @0 |

#### Table Location

Note: \*12~\*0: Table location bits @7~@0: Table pointer bits P12~P8: Current program counter bits

HT48E70

complete the operation. These areas may function as normal program memory depending upon the requirements.

#### Stack Register - STACK

This is a special part of the memory which is used to save the contents of the Program Counter only. The stack is organized into 16 levels and is neither part of the data nor part of the program space, and is neither readable nor writable. The activated level is indexed by the stack pointer (SP) and is neither readable nor writeable. At a subroutine call or interrupt acknowledge signal, the contents of the program counter are pushed onto the stack. At the end of a subroutine or an interrupt routine, signaled by a return instruction (RET or RETI), the program counter is restored to its previous value from the stack. After a chip reset, the SP will point to the top of the stack.

If the stack is full and a non-masked interrupt takes place, the interrupt request flag will be recorded but the acknowledge signal will be inhibited. When the stack pointer is decremented (by RET or RETI), the interrupt will be serviced. This feature prevents stack overflow allowing the programmer to use the structure more easily. In a similar case, if the stack is full and a "CALL" is subsequently executed, stack overflow occurs and the first entry will be lost (only the most recent 16 return addresses are stored).

#### **Data Memory – RAM**

The data memory has a capacity of 256×8 bits and is divided into two functional groups: special function registers and general purpose data memory (224×8). Most are read/write, but some are read only.

The special function registers include the indirect addressing registers (R0;00H, R1;02H), the Bank Pointer (BP;04H), timer/event 0 higher order byte register (TMR0H;0CH), Timer/Event Counter 0 lower order byte register (TMR0L; 0DH) Timer/Event Counter 0 control register (TMR0C;0EH), Timer/Event Counter 1 higher order byte register (TMR1H;0FH), Timer/Event Counter 1 lower order byte register (TMR1L;10H), Timer/Event Counter 1 control register (TMR1C;11H), program counter lower-order byte register (PCL;06H), memory pointer registers (MP0;01H, MP1;03H), accumulator (ACC;05H), table pointer (TBLP;07H), table higher-order byte register (TBLH;08H), status register (STATUS;0AH), interrupt control register (INTC;0BH), Watchdog Timer option setting register (WDTS;09H), I/O registers (PA;12H, PB;14H, PC;16H, PD;18H, PE;1AH, PF;1CH, PG;1EH) and I/O control registers (PAC;13H, PBC;15H, PCC;17H, PDC;19H, PEC;1BH, PFC;1DH, PGC;1FH). The general purpose data memory, addressed from 20H to FFH, is used for data and control information under instruction commands.

#### **RAM Mapping**

All of the data memory areas can handle arithmetic, logic, increment, decrement and rotate operations directly. Except for some dedicated bits, each bit in the data memory can be set and reset by "SET [m].i" and "CLR [m].i". They are also indirectly accessible through memory pointer registers (MP0 or MP1). The control register of the EEPROM data memory is located at [40H] in Bank 1.

#### Indirect Addressing Register

Location 00H and 02H are indirect addressing registers that are not physically implemented. Any read/write operation of [00H] ([02H]) will access data memory pointed to by MP0 (MP1). Reading location 00H (02H) itself indirectly will return the result 00H. Writing indirectly results in no operation.

The memory pointer registers (MP0 and MP1) are 8-bit registers used to access the RAM by combining corresponding indirect addressing registers. MP0 can only be applied to data memory in Bank 0, while MP1 can be applied to data memory in Bank 0 and Bank1.

#### Accumulator

The accumulator is closely related with operations carried out by the ALU. It is mapped to location 05H of the data memory and can carry out immediate data operations. The data movement between two data memory locations must pass through the accumulator.

#### Arithmetic and Logic Unit – ALU

This circuit performs 8-bit arithmetic and logic operations. The ALU provides the following functions:

- Arithmetic operations (ADD, ADC, SUB, SBC, DAA)
- Logic operations (AND, OR, XOR, CPL)
- Rotation (RL, RR, RLC, RRC)
- Increment and Decrement (INC, DEC)
- Branch decision (SZ, SNZ, SIZ, SDZ ....)

The ALU not only saves the results of a data operation but also changes the status register.

#### Status Register – STATUS

This 8-bit register (0AH) contains the zero flag (Z), carry flag (C), auxiliary carry flag (AC), overflow flag (OV), power down flag (PDF), and watchdog time-out flag (TO). It also records the status information and controls the operation sequence.

With the exception of the TO and PDF flags, bits in the status register can be altered by instructions like most other registers. Any data written into the status register will not change the TO or PDF flag. In addition, operations related to the status register may give different results from those intended. The TO flag can be affected only by a system power-up, a WDT time-out or executing the "CLR WDT" or "HALT" instruction. The PDF flag can be affected only by executing the "HALT" or "CLR WDT" instruction or during a system power-up.

The Z, OV, AC and C flags generally reflect the status of the latest operations.

In addition, on entering the interrupt sequence or executing the subroutine call, the status register will not be pushed onto the stack automatically. If the contents of the status are important and if the subroutine can corrupt the status register, precautions must be taken to save it properly.

#### Interrupt

The device provides an external interrupt and internal timer/event counter interrupts. The Interrupt Control Register (INTC;0BH) contains the interrupt control bits to set the enable or disable and the interrupt request flags.

Once an interrupt subroutine is serviced, all the other interrupts will be blocked (by clearing the EMI bit). This scheme may prevent any further interrupt nesting. Other interrupt requests may occur during this interval but only the interrupt request flag is recorded. If a certain interrupt requires servicing within the service routine, the EMI bit and the corresponding bit of the INTC may be set to allow interrupt nesting. If the stack is full, the interrupt request will not be acknowledged, even if the related interrupt is enabled, until the SP is decremented. If immediate service is desired, the stack must be prevented from becoming full.

All these kinds of interrupts have a wake-up capability. As an interrupt is serviced, a control transfer occurs by pushing the program counter onto the stack, followed by a branch to a subroutine at specified location in the program memory. Only the program counter is pushed onto the stack. If the contents of the register or status register (STATUS) are altered by the interrupt service program which corrupts the desired control sequence, the contents should be saved in advance.

| Bit No. | Label | Function  |
|---------|-------|---|
| 0       | С     | C is set if an operation results in a carry during an addition operation or if a borrow does not take place during a subtraction operation; otherwise C is cleared. C is also affected by a rotate through carry instruction. |
| 1       | AC    | AC is set if an operation results in a carry out of the low nibbles in addition or no borrow from the high nibble into the low nibble in subtraction; otherwise AC is cleared.  |
| 2       | Z     | Z is set if the result of an arithmetic or logic operation is zero; otherwise Z is cleared.   |
| 3       | OV    | OV is set if an operation results in a carry into the highest-order bit but not a carry out of the highest-order bit, or vice versa; otherwise OV is cleared.   |
| 4       | PDF   | PDF is cleared by a system power-up or executing the "CLR WDT" instruction. PDF is set by executing the "HALT" instruction.   |
| 5       | то    | TO is cleared by a system power-up or executing the "CLR WDT" or HALT instruction. TO is set by a WDT time-out.   |
| 6, 7    |       | Unused bit, read as "0"   |

#### Status (0AH) Register

| Bit No. | Label | Function   |
|---------|-------|--|
| 0       | EMI   | Controls the master (global) interrupt (1= enabled; 0= disabled)       |
| 1       | EEI   | Controls the external interrupt (1= enabled; 0= disabled)              |
| 2       | ET0I  | Controls the Timer/Event Counter 0 interrupt (1= enabled; 0= disabled) |
| 3       | ET1I  | Controls the Timer/Event Counter 1 interrupt (1= enabled; 0= disabled) |
| 4       | EIF   | External interrupt request flag (1= active; 0= inactive)               |
| 5       | T0F   | Internal Timer/Event Counter 0 request flag (1= active; 0= inactive)   |
| 6       | T1F   | Internal Timer/Event Counter 1 request flag (1= active; 0= inactive)   |
| 7       |       | Unused bit, read as "0"  |

#### INTC (0BH) Register

External interrupts are triggered by a high to low transition of the  $\overline{INT}$  and the related interrupt request flag (EIF; bit 4 of INTC) will be set. When the interrupt is enabled, the stack is not full and the external interrupt is active, a subroutine call to location 04H will occur. The interrupt request flag (EIF) and EMI bits will be cleared to disable other interrupts.

The internal Timer/Event Counter 0 interrupt is initialized by setting the Timer/Event Counter 0 interrupt request flag (T0F; bit 5 of INTC), caused by a timer 0 overflow. When the interrupt is enabled, the stack is not full and the T0F bit is set, a subroutine call to location 08H will occur. The related interrupt request flag (T0F) will be reset and the EMI bit cleared to disable further interrupts.

The internal timer/even counter 1 interrupt is initialized by setting the Timer/Event Counter 1 interrupt request flag (T1F;bit 6 of INTC), caused by a timer 1 overflow. When the interrupt is enabled, the stack is not full and the T1F is set, a subroutine call to location 0CH will occur. The related interrupt request flag (T1F) will be reset and the EMI bit cleared to disable further interrupts.

During the execution of an interrupt subroutine, other interrupt acknowledge signals are held until the "RETI" instruction is executed or the EMI bit and the related interrupt control bit are set to 1 (if the stack is not full). To return from the interrupt subroutine, "RET" or "RETI" may be invoked. RETI will set the EMI bit to enable an interrupt service, but RET will not.

Interrupts, occurring in the interval between the rising edges of two consecutive T2 pulses, will be serviced on the latter of the two T2 pulses, if the corresponding interrupts are enabled. In the case of simultaneous requests the following table shows the priority that is applied. These can be masked by resetting the EMI bit.

| No. | Interrupt Source               | Priority | Vector |
|-----|--------------------------------|----------|--------|
| а   | External Interrupt             | 1        | 04H    |
| b   | Timer/Event Counter 0 Overflow | 2        | 08H    |
| с   | Timer/Event Counter 1 Overflow | 3        | 0CH    |

The Timer/Event Counter 0/1 interrupt request flag (T0F/T1F), external interrupt request flag (EIF), enable

Timer/Event Counter 0/1 interrupt bit (ET0I/ET1I), enable external interrupt bit (EEI) and enable master interrupt bit (EMI) constitute an interrupt control register (INTC) which is located at 0BH in the data memory. EMI, EEI, ET0I and ET1I are used to control the enabling or disabling of interrupts. These bits prevent the requested interrupt from being serviced. Once the interrupt request flags (T0F, T1F, EIF) are set, they will remain in the INTC register until the interrupts are serviced or cleared by a software instruction.

It is recommended that a program does not use the "CALL subroutine" within the interrupt subroutine. Interrupts often occur in an unpredictable manner or need to be serviced immediately in some applications. If only one stack is left and enabling the interrupt is not well controlled, the original control sequence will be damaged once the "CALL" operates in the interrupt subroutine.

#### **Oscillator Configuration**

There are 2 oscillator circuits in the microcontroller.

System Oscillator

All of them are designed for system clocks, namely the external RC oscillator, the external Crystal oscillator, which are determined by options. No matter what oscillator type is selected, the signal provides the system clock. The HALT mode stops the system oscillator and ignores an external signal to conserve power.

If an RC oscillator is used, an external resistor between OSC1 and VDD is required and the resistance must range from  $24k\Omega$  to  $1M\Omega$ . The system clock, divided by 4, is available on OSC2, which can be used to synchronize external logic. The RC oscillator provides the most

cost effective solution. However, the frequency of oscillation may vary with VDD, temperatures and the chip itself due to process variations. It is, therefore, not suitable for timing sensitive operations where an accurate oscillator frequency is desired.

If a Crystal oscillator is used, a crystal across OSC1 and OSC2 is needed to provide the feedback and phase shift required for the oscillator. No other external components are required. In stead of a crystal, a resonator can also be connected between OSC1 and OSC2 to get a frequency reference, but two external capacitors in OSC1 and OSC2 are required.

The WDT oscillator is a free running on-chip RC oscillator, and no external components are required. Even if the system enters the power down mode, the system clock is stopped, but the WDT oscillator still works within a period of approximately 65µs at 5V. The WDT oscillator can be disabled by options to conserve power.

#### Watchdog Timer - WDT

The WDT clock source is implemented by a dedicated RC oscillator (WDT oscillator), instruction clock (system clock divided by 4), determine by options. This timer is designed to prevent a software malfunction or sequence from jumping to an unknown location with unpredictable results. The Watchdog Timer can be disabled by options. If the Watchdog Timer is disabled, all the executions related to the WDT result in no operation.

Once the internal WDT oscillator (RC oscillator with a period of 65µs at 5V normally) is selected, it is first divided by 256 (8-stage) to get the nominal time-out period of 17ms at 5V. This time-out period may vary with temperatures, VDD and process variations. By making use of the WDT prescaler. longer time-out periods can be realized. Writing data to WS2, WS1, WS0 (bit 2,1,0 of the WDTS) can give different time-out periods. If WS2, WS1, and WS0 are all equal to 1, the division ratio is up to 1:128, and the maximum time-out period is 2.1s at 5V seconds. If the WDT oscillator is disabled, the WDT clock may still come from the instruction clock and operates in the same manner except that in the HALT state the WDT may stop counting and lose its protecting purpose. In this situation the logic can only be restarted by external logic. The high nibble and bit 3 of the WDTS are reserved for user-defined flags, which can be used to indicate some specified status.

| WS2 | WS1 | WS0 | Division Ratio |
|-----|-----|-----|----------------|
| 0   | 0   | 0   | 1:1            |
| 0   | 0   | 1   | 1:2            |
| 0   | 1   | 0   | 1:4            |
| 0   | 1   | 1   | 1:8            |
| 1   | 0   | 0   | 1:16           |
| 1   | 0   | 1   | 1:32           |
| 1   | 1   | 0   | 1:64           |
| 1   | 1   | 1   | 1:128          |

If the device operates in a noisy environment, using the

on-chip RC oscillator (WDT OSC) is strongly recom-

# WDTS (09H) Register

The WDT overflow under normal operation will initialize a "chip reset" and set the status bit "TO". But in the HALT mode, the overflow will initialize a "warm reset" and only the Program Counter and SP are reset to zero. To clear the contents of WDT (including the WDT prescaler), three methods are adopted; external reset (a low level to RES), software instruction and a "HALT" instruction. The software instruction includes "CLR WDT" and the other set - "CLR WDT1" and "CLR WDT2". Of these two types of instruction, only one can be active depending upon the option - "CLR WDT times selection option". If the "CLR WDT" is selected (i.e. CLRWDT times equal one), any execution of the "CLR WDT" instruction will clear the WDT. In the case that "CLR WDT1" and "CLR WDT2" are chosen (i.e. CLRWDT times equal two), these two instructions must be executed to clear the WDT; otherwise, the WDT may reset the chip as a result of time-out.

#### **Power Down Operation – HALT**

The HALT mode is initialized by a "HALT" instruction and results in the following...

- The system oscillator will be turned off but the WDT oscillator remains running (if the WDT oscillator is selected).
- The contents of the on chip RAM and registers remain unchanged.
- WDT and WDT prescaler will be cleared and recounted again (if the WDT clock is from the WDT oscillator).

#### Watchdog Timer

- All of the I/O ports maintain their original status.
- The PDF flag is set and the TO flag is cleared.

The system can leave the HALT mode by means of an external reset, an interrupt, an external falling edge signal on port A or a WDT overflow. An external reset causes a device initialization and the WDT overflow performs a "warm reset". After the TO and PDF flags are examined, the reason for chip reset can be determined. The PDF flag is cleared by system power-up or executing the "CLR WDT" instruction and is set when executing the "HALT" instruction. The TO flag is set if the WDT time-out occurs, and causes a wake-up that only resets the Program Counter and SP; the others remain in their original status.

The port A wake-up and interrupt methods can be considered as a continuation of normal execution. Each bit in port A can be independently selected to wake-up the device by options. Awakening from an I/O port stimulus, the program will resume execution of the next instruction. If it awakens from an interrupt, two sequence may occur. If the related interrupt is disabled or the interrupt is enabled but the stack is full, the program will resume execution at the next instruction. If the interrupt is enabled and the stack is not full, the regular interrupt response takes place. If an interrupt request flag is set to "1" before entering the HALT mode, the wake-up function of the related interrupt will be disabled. Once a wake-up event occurs, it takes 1024 texes (system clock period) to resume normal operation. In other words, a dummy period will be inserted after a wake-up. If the wake-up results from an interrupt acknowledge signal, the actual interrupt subroutine execution will be delayed by one or more cycles. If the wake-up results in the next instruction execution, this will be executed immediately after the dummy period is finished.

To minimize power consumption, all the I/O pins should be carefully managed before entering the HALT status.

#### Reset

There are three ways in which a reset can occur:

- RES reset during normal operation
- RES reset during HALT
- WDT time-out reset during normal operation

The WDT time-out reset during HALT mode is different from other chip reset conditions, since it can perform a "warm reset" that resets only the Program Counter and SP, leaving the other circuits in their original state. Some registers remain unchanged during other reset conditions. Most registers are reset to the "initial condition" when the reset conditions are met. By examining the PDF and TO flags, the program can distinguish between different "chip resets".

| то | PDF | RESET Conditions                                |
|----|-----|---|
| 0  | 0   | RES reset during power-on                       |
| u  | u   | RES reset during normal operation               |
| 0  | 1   | RES wake-up from HALT mode                      |
| 1  | u   | WDT time-out reset during normal opera-<br>tion |
| 1  | 1   | WDT wake-up from HALT mode                      |

Note: "u" stands for "unchanged"

To guarantee that the system oscillator is started and stabilized, the SST (System Start-up Timer) provides an extra-delay of 1024 system clock pulses when the system reset (power-up, WDT time-out or  $\overline{\text{RES}}$  reset) or the system awakes from the HALT state.

When a system reset occurs, the SST delay is added during the reset period. Any wake-up from HALT will enable the SST delay.

Note: "\*" Make the length of the wiring, which is connected to the RES pin as short as possible, to avoid noise interference.

**Reset Configuration** 

An extra option load time delay is added during system reset (power-up, WDT time-out at normal mode or RES reset).

| Program Counter     | 000H   |
|---------------------|--|
| Interrupt           | Disable  |
| Prescaler           | Clear  |
| WDT                 | Clear. After master reset, WDT begins counting |
| Timer/Event Counter | Off  |
| Input/Output Ports  | Input mode                                     |
| SP                  | Points to the top of the stack                 |

### The states of the registers is summarized in the table.

| Register           | Reset<br>(Power On) | WDT Time-out<br>(Normal Operation) | RES Reset<br>(Normal Operation) | RES Reset<br>(HALT) | WDT Time-out<br>(HALT)* |
|--------------------|---------------------|------------------------------------|---------------------------------|---------------------|-------------------------|

"u" stands for "unchanged"

"x" stands for "unknown"

#### **Timer/Event Counter**

Two timer/event counters (TMR0, TMR1) are implemented in the microcontroller. The Timer/Event Counter 0 contains a 16-bit programmable count-up counter and the clock may come from an external source or from the system clock divided by 4.

The Timer/Event Counter 1 contains a 16-bit programmable count-up counter and the clock may come from an external source or from the system clock divided by 4.

Using the external clock input allows the user to count external events, measure time intervals or pulse widths, or generate an accurate time base. While using the internal clock allows the user to generate an accurate time base.

There are 3 registers related to the Timer/Event Counter 0;TMR0H ([0CH]), TMR0L ([0DH]), TMR0C ([0EH]). Writing TMR0L will only put the written data to an internal lower-order byte buffer (8 bits) and writing TMR0H will transfer the specified data and the contents of the lower-order byte buffer to TMR0H and TMR0L preload registers, respectively. The Timer/Event Counter 1 preload register is changed by each writing TMR0H operations. Reading TMR0H will latch the contents of TMR0H and TMR0L counters to the destination and the lower-order byte buffer, respectively. Reading the TMR0L will read the contents of the lower-order byte buffer. The TMR0C is the Timer/Event Counter 1 control register, which defines the operating mode, counting enable or disable and active edge.

There are 3 registers related to the Timer/Event Counter 1; TMR1H (0FH), TMR1L (10H), TMR1C (11H). Writing TMR1L will only put the written data to an internal lower-order byte buffer (8 bits) and writing TMR1H will transfer the specified data and the contents of the lower-order byte buffer to TMR1H and TMR1L preload registers respectively. The Timer/Event Counter 1 preload register is changed by each writing TMR1H operations. Reading TMR1H will latch the contents of TMR1H and TMR1L counters to the destination and the lower-order byte buffer, respectively. Reading the TMR1L will read the contents of the lower-order byte buffer. The TMR1C is the Timer/Event Counter 1 control register, which defines the operating mode, counting enable or disable and active edge.

The T0M0, T0M1, T1M0, T1M1 bits define the operating mode. The event count mode is used to count external events, which means the clock source comes from an external (TMR0/TMR1) pin. The timer mode functions as a normal timer with the clock source coming from the

| Bit No. | Label        | Function  |  |
|---------|--------------|---|--|
| 0~2     |              | Unused bit, read as "0"   |  |
| 3       | T0E          | Defines the TMR0 active edge of the Timer/Event Counter 0<br>(0=active on low to high; 1=active on high to low)   |  |
| 4       | T0ON         | Enable or disable timer 0 counting (0=disabled; 1=enabled)  |  |

#### TMR0C (0EH) Register

| Bit No. | Label        | Function  |  |
|---------|--------------|---|--|
| 0~2     |              | Unused bit, read as "0"   |  |
| 3       | T1E          | Defines the TMR1 active edge of the Timer/Event Counter 1<br>(0=active on low to high; 1=active on high to low)   |  |
| 4       | T1ON         | nable or disable timer 1 counting (0=disabled; 1=enabled)   |  |
| 5       |              | Inused bit, read as "0"   |  |
| 6<br>7  | T1M0<br>T1M1 | Defines the operating mode (T1M1, T1M0)<br>01=Event count mode (external clock)<br>10=Timer mode (internal clock)<br>11=Pulse width measurement mode<br>00=Unused |  |

#### TMR1C (11H) Register

instruction clock (Timer1). The pulse width measurement mode can be used to count the high or low level duration of the external signal (TMR0/TMR1). The counting is based on the instruction clock (Timer1).

In the event count or timer mode, once the Timer/Event Counter 0/1 starts counting, it will count from the current contents in the Timer/Event Counter 0/1 to FFFFH. Once overflow occurs, the counter is reloaded from the Timer/Event Counter 0/1 preload register and generates the interrupt request flag (T0F/T1F; bit 5/6 of INTC) at the same time.

In the pulse width measurement mode with the T0ON/T1ON and T0E/T1E bits equal to one, once the TMR0/TMR1 has received a transient from low to high (or high to low if the TE bits is "0") it will start counting until the TMR0/TMR1 returns to the original level and resets the T0ON/T1ON. The measured result will remain in the Timer/Event Counter 0/1 even if the activated transient occurs again. In other words, only one cycle measurement can be done. Until setting the T0ON/T1ON, the cycle measurement will function again as long as it receives further transient pulse. Note that, in this operating mode, the Timer/Event Counter 0/1 starts counting not according to the logic level but according to the transient edges. In the case of counter

overflows, the counter 0/1 is reloaded from the Timer/Event Counter 0/1 preload register and issues the interrupt request just like the other two modes. To enable the counting operation, the timer ON bit (T0ON/T1ON; bit 4 of TMR0C/TMR1C) should be set to 1. In the pulse width measurement mode, the T0ON/T1ON will be cleared automatically after the measurement cycle is completed. But in the other two modes the T0ON/T1ON can only be reset by instructions. The overflow of the Timer/Event Counter 0/1 is one of the wake-up sources. No matter what the operation mode is, writing a 0 to ET0I/ET1I can disable the corresponding interrupt services.

In the case of Timer/Event Counter 0/1 OFF condition, writing data to the Timer/Event Counter 0/1 preload register will also reload that data to the Timer/Event Counter 0/1. But if the Timer/Event Counter 0/1 is turned on, data written to it will only be kept in the Timer/Event Counter 0/1 preload register. The Timer/Event Counter 0/1 will still operate until overflow occurs (a Timer/Event Counter 0/1 reloading will occur at the same time). When the Timer/Event Counter 0/1 (reading TMR0/TMR1) is read, the clock will be blocked to avoid errors. As clock blocking may result in a counting error, this must be taken into consideration by the programmer.

**Timer/Event Counter 0** 

**Timer/Event Counter 1** 

#### Input/Output Ports

There are 56 bidirectional input/output lines in the microcontroller, labeled from PA to PG, which are mapped to the data memory of [12H], [14H], [16H], [18H], [1AH], [1CH] and [1EH] respectively. All of these I/O ports can be used for input and output operations. For input operation, these ports are non-latching, that is, the inputs must be ready at the T2 rising edge of instruction "MOV A,[m]" (m=12H, 14H, 16H, 18H, 1AH, 1CH or 1EH). For output operation, all the data is latched and remains unchanged until the output latch is rewritten.

Each I/O line has its own control register (PAC, PBC, PCC, PDC, PEC, PFC, PGC) to control the input/output configuration. With this control register, CMOS output or Schmitt trigger input with or without pull-high resistor structures can be reconfigured dynamically under software control. To function as an input, the corresponding latch of the control register must write a "1". The input source also depends on the control register. If the control register bit is "1", the input will read the pad state. If the control register bit is "0", the contents of the latches will move to the internal bus. The latter is possible in the "read-modify-write" instruction.

For output function, CMOS is the only configuration. These control registers are mapped to locations 13H, 15H, 17H, 19H, 1BH, 1DH and 1FH.

After a chip reset, these input/output lines remain at high levels or floating state (depending on the pull-high options). Each bit of these input/output latches can be set or cleared by "SET [m].i" and "CLR [m].i" (m=12H, 14H, 16H, 18H, 1AH, 1CH or 1EH) instructions.

Some instructions first input data and then follow the output operations. For example, "SET [m].i", "CLR [m].i", "CPL [m]", "CPLA [m]" read the entire port states into the CPU, execute the defined operations (bit-operation), and then write the results back to the latches or the accumulator.

Each line of port A has the capability of waking-up the device.

There is a pull-high option available for all I/O lines (port option). Once the pull-high option of an I/O line is selected, the I/O line has a pull-high resistor. Otherwise, the pull-high resistor is absent. It should be noted that a non-pull-high I/O line operating in input mode will cause a floating state.

#### Low Voltage Reset – LVR

The microcontroller provides a low voltage reset circuit in order to monitor the supply voltage of the device. If the supply voltage of the device drops to within the range of  $0.9V \sim V_{LVR}$ , such as might occur when changing the battery, the LVR will automatically reset the device internally.

The LVR includes the following specifications:

- A low voltage  $(0.9V \sim V_{LVR})$  must exist for greater than 1ms. If the low voltage state does not exceed 1ms, the LVR will ignore it and will not perform a reset function.
- The LVR uses the "OR" function with the external  $\overrightarrow{\text{RES}}$  signal to perform chip reset.

The relationship between  $V_{\text{DD}}$  and  $V_{\text{LVR}}$  is shown below.

- Note: \*1: To make sure that the system oscillator has stabilized, the SST provides an extra delay of 1024 system clock pulses before entering the normal operation.
  - \*2: Since low voltage has to be maintained in its original state and exceed 1ms, therefore 1ms delay enters the reset mode.

#### **EEPROM Data Memory**

The 256×8 bits EEPROM data memory is readable and writable during normal operation. It is indirectly addressed through the control register EECR ([40H] in Bank 1). The EECR can be read and written to only by indirect addressing mode using MP1.

| Bit No. | Label | Function                                   |  |
|---------|-------|--|--|
| 0~3     |       | Unused bit, read as "0"                    |  |
| 4       | CS    | EEPROM data memory select                  |  |
| 5       | SK    | erial clock input to EEPROM data memory    |  |
| 6       | DI    | Serial data input to EEPROM data memory    |  |
| 7       | DO    | Serial data output from EEPROM data memory |  |

#### EECR (40H) Register

EEPROM Data Memory Block Diagram

The EEPROM data memory is accessed via a three-wire serial communication interface by writing to EECR. It is arranged into 256 words by 8 bits. The EEPROM data memory contains seven instructions: READ, ERASE, WRITE, EWEN, EWDS, ERAL and WRAL. These instructions are all made up of 12 bits data: 1 start bit, 2 op-code bits and 9 address bits.

By writing CS, SK and DI, these instructions can be transmitted to the EEPROM. These serial instruction data presented at the DI will be written into the

EEPROM data memory at the rising edge of SK. During the READ cycle, DO acts as the data output and during the WRITE or ERASE cycle, DO indicates the BUSY/READY status. When the DO is active for read data or as a BUSY/ READY indicator the CS pin must be high; otherwise DO will be in a high state. For successful instructions, CS must be low once after the instruction is sent. After power on, the device is by default in the EWDS state. An EWEN instruction must be performed before any ERASE or WRITE instruction can be executed.

The following are the functional descriptions and timing diagrams of all seven instructions.

EECR A.C. Characteristics

| t <sub>PR</sub>  | Write Cycle Time Per Word | _                       | 2    | _                         | 5    | ms   |

### READ

The READ instruction will stream out data at a specified address on the DO. The data on DO changes during the low-to-high edge of SK. The 8 bits data stream is preceded by a logical "0" dummy bit. Irrespective of the condition of the EWEN or EWDS instruction, the READ command is always valid and independent of these two instructions. After the data word has been read the internal address will be automatically incremented by 1, allowing the next consecutive data word to be read out without entering further address data. The address will wrap around with CS High until CS returns to Low.

# EWEN/EWDS

The EWEN/EWDS instruction will enable or disable the programming capabilities. At both the power on and power off state the device automatically enters the disable mode. Before a WRITE, ERASE, WRAL or ERAL instruction is given, the programming enable instruction EWEN must be issued, otherwise the ERASE/WRITE instruction is invalid. After the EWEN instruction is issued, the programming enable condition remains until power is turned off or an EWDS instruction is issued. No data can be written into the EEPROM data memory in the programming disabled state. By so doing, the internal memory data can be protected.

# ERASE

The ERASE instruction erases data at the specified addresses in the programming enable mode. After the ERASE op-code and the specified address have been issued, the data erase is activated by the falling edge of CS. Since the internal auto-timing generator provides all timing signals for the internal erase, so the SK clock is not required. During the internal erase, we can verify the busy/ready status if CS is high. The DO will remain low but when the operation is over, the DO will return to high and further instructions can be executed.

# WRITE

The WRITE instruction writes data into the EEPROM data memory at the specified addresses in the programming enable mode. After the WRITE op-code and the specified address and data have been issued, the data writing is activated by the falling edge of CS. Since the internal auto-timing generator provides all timing signal for the internal writing, so the SK clock is not required. The auto-timing write cycle includes an automatic erase-before-write capability. So, it is not necessary to erase data before the WRITE instruction. During the internal writing, we can verify the busy/ready status if CS is high. The DO will remain low but when the operation is over, the DO will return to high and further instructions can be executed.

**EECR Control Timing Diagrams** 

#### ERAL

The ERAL instruction erases the entire 256×8 memory cells to a logical "1" state in the programming enable mode. After the erase-all instruction set has been issued, the data erase feature is activated by a falling edge of CS. Since the internal auto-timing generator provides all timing signal for the erase-all operation, so the SK clock is not required. During the internal erase-all operation, we can verify the busy/ready status if CS is high. The DO will remain low but when the operation is over, the DO will return to high and further instruction can be executed.

### WRAL

The WRAL instruction writes data into the entire 256×8 memory cells in the programming enable mode. After the write-all instruction set has been issued, the data writing is activated by a falling edge of CS. Since the internal auto-timing generator provides all timing signals for the write-all operation, so the SK clock is not required. During the internal write-all operation, we can verify the busy/ready status if CS is high. The DO will remain low but when the operation is over the DO will return to high and further instruction can be executed.

# EEPROM Data Memory Instruction Set Summary

| Instruction | Comments            | Start bit | Op Code | Address   | Data  |
|-------------|---------------------|-----------|---------|-----------|-------|
| READ        | Read data           | 1         | 10      | X, A7~A0  | D7~D0 |
| ERASE       | Erase data          | 1         | 11      | X, A7~A0  |       |
| WRITE       | Write data          | 1         | 01      | X, A7~A0  | D7~D0 |
| EWEN        | Erase/Write Enable  | 1         | 00      | 11XXXXXXX |       |
| EWDS        | Erase/Write Disable | 1         | 00      | 00XXXXXXX | _     |
| ERAL        | Erase All           | 1         | 00      | 10XXXXXXX | _     |
| WRAL        | Write All           | 1         | 00      | 01XXXXXXX | D7~D0 |

Note: "X" stands for "don't care"

# Options

The following table shows all kinds of options in the microcontroller. All of the options must be defined to ensure a properly functioning system.

| No. | Options   |
|-----|---|
| 1   | WDT clock source: WDT oscillator or $f_{\mbox{SYS}}/4$ or disable |
| 2   | CLRWDT instructions: 1 or 2 instructions                          |
| 3   | Timer/Event Counter 0 clock sources: f <sub>SYS</sub> /4          |
| 4   | Timer/Event Counter 1 clock sources: f <sub>SYS</sub> /4          |
| 5   | PA wake-up (By bit)   |
| 6   | PA CMOS or Schmitt input  |
| 7   | PA, PB, PC, PD, PE, PF, PG pull-high enable or disable (By port)  |
| 8   | BZ/BZ enable or disable   |
| 9   | BZ/BZ source: TMR0 or TMR1  |
| 10  | System oscillator: RC or crystal                                  |
| 11  | WDT enable or disable   |
| 12  | LVR enable or disable   |

# **Application Circuits**

Note: The resistance and capacitance for reset circuit should be designed in such a way as to ensure that the VDD is stable and remains within a valid operating voltage range before bringing RES to high.

"\*" Make the length of the wiring, which is connected to the RES pin as short as possible, to avoid noise interference.

The following table shows the C1, C2 and R1 values corresponding to the different crystal values. (For reference only)

| Crystal or Resonator  | C1, C2 | R1    |  |  |
|---|--------|-------|--|--|
| 4MHz Crystal  | 0pF    | 10kΩ  |  |  |
| 4MHz Resonator (3 pin)  | 0pF    | 12kΩ  |  |  |
| 4MHz Resonator (2 pin)  | 10pF   | 12kΩ  |  |  |
| 3.58MHz Crystal   | 0pF    | 10kΩ  |  |  |
| 3.58MHz Resonator (2 pin)   | 25pF   | 10kΩ  |  |  |
| 2MHz Crystal & Resonator (2 pin)  | 25pF   | 10kΩ  |  |  |
| 1MHz Crystal  | 35pF   | 27kΩ  |  |  |
| 480kHz Resonator  | 300pF  | 9.1kΩ |  |  |
| 455kHz Resonator  | 300pF  | 10kΩ  |  |  |
| 429kHz Resonator 300pF 10kΩ   |        |       |  |  |
| The function of the resistor R1 is to ensure that the oscillator will switch off should low voltage condi-<br>tions occur. Such a low voltage, as mentioned here, is one which is less than the lowest value of the<br>MCU operating voltage. Note however that if the LVR is enabled then R1 can be removed. |        |       |  |  |

#### Note: x: Immediate data

m: Data memory address

A: Accumulator

i: 0~7 number of bits

addr: Program memory address

- $\sqrt{}$ : Flag is affected
- -: Flag is not affected
- <sup>(1)</sup>: If a loading to the PCL register occurs, the execution cycle of instructions will be delayed for one more cycle (four system clocks).
- <sup>(2)</sup>: If a skipping to the next instruction occurs, the execution cycle of instructions will be delayed for one more cycle (four system clocks). Otherwise the original instruction cycle is unchanged.
- $^{(3)}$ :  $^{(1)}$  and  $^{(2)}$
- <sup>(4)</sup>: The flags may be affected by the execution status. If the Watchdog Timer is cleared by executing the "CLR WDT1" or "CLR WDT2" instruction, the TO and PDF are cleared. Otherwise the TO and PDF flags remain unchanged.

# Instruction Definition

| ADC A,[m]        | Add data  | memory a                  | nd carry to  | the accu     | mulator      |              |  |  |
|------------------|---|---------------------------|--------------|--------------|--------------|--------------|--|--|
| Description      | The contents of the specified data memory, accumulator and the carry flag are added a multaneously, leaving the result in the accumulator.            |                           |              |              |              |              |  |  |

| DAA [m]       Decimal-Adjust accumulator for addition         Description       The accumulator value is adjusted to the BCD (Binary Coded Decimal) code. The accumulator is divided into two nibbles. Each nibble is adjusted to the BCD code and an inter carry (AC1) will be done if the low nibble of the accumulator is greater than 9. The BCD justment is done by adding 6 to the original value is greater than 9 or carry (AC or C) is set; otherwise the original value is greater than 9 or carry (AC or C) is set; otherwise the original value remains unchanged. The result is store in the data memory and only the carry flag (C) may be affected.         Operation       If ACC.3~ACC.0.9 or AC=1         then [m].3~[m].0 \leftarrow (ACC.3~ACC.0)+6, AC1=AC         else [m].3~[m].0 \leftarrow (ACC.3~ACC.0), AC1=0         and       If ACC.7~ACC.4+AC1.9 or C=1         then [m].7~[m].4 ← ACC.7~ACC.4+6+AC1,C=1         else [m].7~[m].4 ← ACC.7~ACC.4+6+AC1,C=C         Affected flag(s)       To       PDF       OV       Z       AC       C         Decrement data memory       Decremented by 1.
