Raytheon

Micro-Power Operational Amplifier

RC3078, RM3078A

Features

- Low standby power — as low as 700nW
- Wide supply voltage range — ±0.75V to ±15V
- High peak output current — 6.5mA minimum
- Adjustable quiescent current
- Output short circuit protection

Applications

- Portable electronics
- Medical electronics
- Instrumentation
- Telemetry

Description

The 3078 and 3078A are high gain monolithic operational amplifiers which can deliver milliamperes of current yet only consume microwatts of standby power. Their operating points are externally adjustable and frequency compensation may be accomplished with one external capacitor. The 3078 and 3078A provide the designer with the opportunity to tailor the frequency response and improve the slew rate without sacrificing power. Operation with a single 1.5V battery is a practical reality with these devices.

The 3078A is a premium device having a supply voltage range of V_S = ±0.75V to V_S = ±15V and an operating temperature range of -55° C to +125° C. The 3078 has the same lower supply voltage limit but the upper limit is $+V_S$ = +6V and $-V_S$ = -6V. The operating temperature range is from 0° C to +70° C

Operating Considerations

The 3078 and 3078A can be phase-compensated with one or two external components depending upon the closed-loop gain, power consumption, and speed desired. The recommended compensation is a resistor in series with a capacitor connected from terminal 1 to terminal 8. Values of the resistor and capacitor as required for compensation are a function of closed-loop gain. These curves represent the compensation necessary at quiescent currents of 20μA and 100μA, respectively, for a transient with 10% overshoot. The slew rates curves show what can be obtained with the two different compensation techniques. Higher speeds can be achieved with input compensation, but this increases noise output. Compensation can also be accomplished with a single capacitor connected from terminal 1 to terminal 8, with speed being sacrificed for simplicity. Table 1 gives an indication of slew rates that can be obtained with various compensation techniques at quiescent currents of 20μA and 100μA.

Single Supply Operation

The 3078 and 3078A can operate from a single supply with a minimum total supply voltage of 1.5V. Figures 2 and 3 show the 3078 and 3078A in inverting and non-inverting 20dB amplifier configurations utilizing a 1.5V type "A" cell for a supply. The total power consumption for either circuit is approximately 675 nanowatts. The output voltage swing in this configuration is $300mV_{p-p}$ with a 20kΩ load.

Table 1. Unity Gain Slew Rate Versus Compensation — 3078 and 3078A
