Sound 24-Bit, 192kHz Sampling,6-Channel, Enhanced Multi-Level, Delta-Sigma DIGITAL-TO-ANALOG CONVERTER

FEATURES

- PIN COMPATIBLE WITH PCM1600, PCM1601
- 24-BIT RESOLUTION
- ANALOG PERFORMANCE: Dynamic Range: 105dB typ SNR: 104dB typ THD+N: 0.0018% typ Full-Scale Output: 3.1Vp-p typ
- 8x OVERSAMPLING INTERPOLATION FILTER: Stopband Attenuation: –82dB Passband Ripple: ±0.002dB
- SAMPLING FREQUENCY: 10kHz to 200kHz
- ACCEPTS 16-, 18-, 20-, AND 24-BIT AUDIO DATA
- DATA FORMATS: Standard, I²S, and Left-Justified
- SYSTEM CLOCK: 128/192/256/384/512/768f_S
- USER-PROGRAMMABLE FUNCTIONS: Digital Attenuation: 0dB to -63dB, 0.5dB/Step Soft Mute

Zero Detect Mute

Zero Flags May Be Used As General Purpose Logic Outputs Digital De-Emphasis

Digital Filter Roll-Off: Sharp or Slow

- DUAL SUPPLY OPERATION: +5V Analog, +3.3V Digital
- 5V TOLERANT DIGITAL LOGIC INPUTS
- PACKAGES⁽¹⁾: LQFP-48 (PCM1604) and MQFP-48 (PCM1605)

APPLICATIONS

- INTEGRATED A/V RECEIVERS
- DVD MOVIE AND AUDIO PLAYERS
- HDTV RECEIVERS
- CAR AUDIO SYSTEMS
- DVD ADD-ON CARDS FOR HIGH-END PCs
- DIGITAL AUDIO WORKSTATIONS
- OTHER MULTI-CHANNEL AUDIO SYSTEMS

DESCRIPTION

The PCM1604⁽¹⁾ and PCM1605⁽¹⁾ are CMOS monolithic integrated circuits which feature six 24-bit audio digital-to-analog converters, and support circuitry in a small QFP-48 package. The digital-to-analog converters utilize Burr-Brown's enhanced multi-level, deltasigma architecture, which employs 4th-order noise shaping and 8-level amplitude quantization to achieve excellent signal-to-noise performance, and a high tolerance to clock jitter.

The PCM1604 and PCM1605 accept industry-standard audio data formats with 16- to 24-bit audio data. Sampling rates up to 200kHz are supported. A full set of user-programmable functions are accessible through a 4-wire serial control port which supports register write and readback functions.

NOTE: (1) The PCM1604 and PCM1605 utilize the same die and are electrically identical. All references to the PCM1604 apply equally to the PCM1605.

ELECTROSTATIC DISCHARGE SENSITIVITY

This integrated circuit can be damaged by ESD. Burr-Brown recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

47	DATA3	I	Serial Audio Data Input for $V_{OUT} 5$ and $V_{OUT} 6^{(2)}$
48	ZEROA	0	Zero Data Flag. Logical "AND" of ZERO1 through ZERO6.

NOTES: (1) Schmitt-Trigger input with internal pull-down, 5V tolerant. (2) Schmitt-Trigger input, 5V tolerant. (3) Tri-state output.

TYPICAL PERFORMANCE CURVES

All specifications at +25°C, V_{CC} = 5V, V_{DD} = 3.3V, SYSCLK = 384f_S (f_S = 44.1kHz), and 24-bit input data, unless otherwise noted.

DIGITAL FILTER

Digital Filter (De-Emphasis Off, f_s = 44.1kHz)

Fre

(kHz)

All specifications at +25°C, V_{CC} = 5V, V_{DD} = 3.3V, SYSCLK = 384f_S (f_S = 44.1kHz), and 24-bit input data, unless otherwise noted.

ANALOG DYNAMIC PERFORMANCE

All specifications at V_{DD} = +3.3V, 128f_S system clock, 64x oversampling, and 24-bit data. Only two channels (V_{OUT} 1 and V_{OUT} 2) are operated. All other channels are set to all zero input data and DAC operation is disabled (bits DAC3 through DAC6 of Register 8 are set to 1).

All specifications at +25°C, V_{CC} = 5V, V_{DD} = 3.3V, SYSCLK = 384f_S (f_S = 44.1kHz), and 24-bit input data, unless otherwise noted.

ANALOG DYNAMIC PERFORMANCE (Cont.) Temperature Characteristics

All specifications at $V_{CC} = +5V$, $V_{DD} = +3.3V$, 128f_S system clock, 64x oversampling, and 24-bit data. Only two channels (V_{OUT} 1 and V_{OUT} 2) are operated. All other channels are set to all zero input data and DAC operation is disabled (bits DAC3 through DAC6 of Register 8 are set to 1).

SYSTEM CLOCK AND RESET FUNCTIONS

SYSTEM CLOCK INPUT

The PCM1604 and PCM1605 require a system clock for operating the digital interpolation filters and multi-level delta-sigma modulators. The system clock is applied at the SCKI input (pin 38). Table I shows examples of system clock frequencies for common audio sampling rates.

Figure 1 shows the timing requirements for the system clock input. For optimal performance, it is important to use a clock source with low phase jitter and noise. Burr-Brown's PLL1700 multi-clock generator is an excellent choice for providing the PCM1604 system clock source.

To obtain optimal dynamic performance when operating with a 192kHz sampling frequency, it is recommended that only two channels be enabled for operation (V_{OUT} 1 and V_{OUT} 2). The remaining four channels should be disabled by setting bits DAC3 through DAC6 of control register 8 to logic 1 state.

SYSTEM CLOCK OUTPUT

A buffered version of the system clock input is available at the SCKO output (pin 39). SCKO can operate at either full (f_{SCKI}) or half ($f_{SCKI}/2$) rate. The SCKO output frequency may be programmed using the CLKD bit of Control Register 9. The SCKO output pin can also be enabled or disabled using the CLKE bit of Control Register 9. The default is SCKO enabled.

POWER-ON AND EXTERNAL RESET FUNCTIONS

The PCM1604 includes a power-on reset function. Figure 2 shows the operation of this function.

The system clock input at SCKI should be active for at least one clock period prior to $V_{DD} = 2.0V$. With the system clock active and $V_{DD} > 2.0V$, the power-on reset function will be enabled. The initialization sequence requires 1024 system clocks from the time $V_{DD} > 2.0V$. After the initialization period, the PCM1604 will be set to its reset default state, as described in the Mode Control Register section of this data sheet.

The PCM1604 also includes an external reset capability using the $\overline{\text{RST}}$ input (pin 37). This allows an external controller or master reset circuit to force the PCM1604 to initialize to its reset default state. For normal operation, $\overline{\text{RST}}$ should be set to a logic '1'.

Figure 3 shows the external reset operation and timing. The $\overline{\text{RST}}$ pin is set to logic '0' for a minimum of 20ns. The $\overline{\text{RST}}$ pin is then set to a logic '1' state, which starts the initialization sequence, which lasts for 1024 system clock periods. After the initialization sequence is completed, the PCM1604 will be set to its reset default state, as described in the Mode Control Registers section of this data sheet.

The external reset is especially useful in applications where there is a delay between PCM1604 power up and system clock activation. In this case, the \overrightarrow{RST} pin should be held at a logic '0' level until the system clock has been activated.

	SYSTEM CLOCK FREQUENCY (f _{SCKI}) (MHz)

AUDIO SERIAL INTERFACE

The audio serial interface for the PCM1604 is comprised of a 5-wire synchronous serial port. It includes LRCK (pin 41), BCK (pin 40), DATA1 (pin 45), DATA2 (pin 46) and DATA3 (pin 47). BCK is the serial audio bit clock, and is used to clock the serial data present on DATA1, DATA2 and DATA3 into the audio interface's serial shift registers. Serial data is clocked into the PCM1604 on the rising edge of BCK. LRCK is the serial audio left/right word clock. It is used to latch serial data into the serial audio interface's internal registers.

Both LRCK and BCK must be synchronous to the system clock. Ideally, it is recommended that LRCK and BCK be derived from the system clock input or output, SCKI or SCKO. The left/right clock, LRCK, is operated at the sampling frequency (f_s). The bit clock, BCK, may be operated at 48 or 64 times the sampling frequency.

AUDIO DATA FORMATS AND TIMING

The PCM1604 supports industry-standard audio data formats, including Standard, I²S, and Left-Justified. The data formats are shown in Figure 4. Data formats are selected using the format bits, FMT[2:0], in Control Register 9. The default data format is 24-bit Standard. All formats require Binary Two's Complement, MSB-first audio data. Figure 5 shows a detailed timing diagram for the serial audio interface. DATA1, DATA2 and DATA3 each carry two audio channels, designated as the Left and Right channels. The Left channel data always precedes the Right channel data in the serial data stream for all data formats. Table II shows the mapping of the digital input data to the analog output pins.

DATA INPUT	CHANNEL	ANALOG OUTPUT
DATA1	L eft	Vour1
DATA1	Right	V ₀₁₁ 2
DATA2	Left	V _{OUT} 3
DATA2	Right	V _{OUT} 4
DATA3	Left	V _{OUT} 5
DATA3	Right	V _{OUT} 6

ГАВLE II. Audio Input Data to Analog Outp	ut Mapping.
---	-------------

SERIAL CONTROL INTERFACE

The serial control interface is a 4-wire synchronous serial port which operates asynchronously to the serial audio interface. The serial control interface is utilized to program and read the on-chip mode registers. The control interface includes MDO (pin 33), MDI (pin 34), MC (pin 35), and ML (pin 36). MDO is the serial data output, used to read back the values of the mode registers; MDI is the serial data input, used to program the mode registers; MC is the serial bit clock, used to shift data in and out of the control port and ML is the control port latch clock.

FIGURE 4. Audio Data Input Formats.

FIGURE 5. Audio Interface Timing.

FIGURE 6. Control Data Word Format for MDI.

FIGURE 7. Write Operation Timing.

REGISTER WRITE OPERATION

All Write operations for the serial control port use 16-bit data words. Figure 6 shows the control data word format. The most significant bit is the Read/Write (R/W) bit. When set to '0', this bit indicates a Write operation. There are seven bits, labeled IDX[6:0], that set the register index (or address) for the Write operation. The least significant eight bits, D[7:0], contain the data to be written to the register specified by IDX[6:0].

Figure 7 shows the functional timing diagram for writing the serial control port. ML is held at a logic '1' state until a register needs to be written. To start the register write cycle, ML is set to logic '0'. Sixteen clocks are then provided on MC, corresponding to the 16-bits of the control data word on MDI. After the sixteenth clock cycle has completed, ML is set to logic '1' to latch the data into the indexed mode control register.

SINGLE REGISTER READ OPERATION

Read operations utilize the 16-bit control word format shown in Figure 6. For Read operations, the Read/Write (R/W) bit is set to '1'. Read operations ignore the index bits, IDX[6:0], of the control data word. Instead, the REG[6:0] bits in Control Register 11 are used to set the index of the register that is to be read during the Read operation. Bits IDX[6:0] should be set to $00_{\rm H}$ for Read operations.

Figure 8 details the Read operation. First, Control Register 11 must be written with the index of the register to be read back. Additionally, the INC bit must be set to logic '0' in order to disable the Auto-Increment Read function. The Read cycle is then initiated by setting ML to logic '0' and setting the R/W bit of the control data word to logic '1', indicating a Read operation. MDO remains at a high-impedance state until the

FIGURE 9. Read Operation Timing with INC = 1 (Auto-Increment Read).

last 8 bits of the 16-bit read cycle, which corresponds to the 8 data bits of the register indexed by the REG[6:0] bits of Control Register 11. The Read cycle is completed when ML is set to '1', immediately after the MC clock cycle for the least significant bit of indexed control register has completed.

AUTO-INCREMENT READ OPERATION

The Auto-Increment Read function allows for multiple registers to be read sequentially. The Auto-Increment Read function is enabled by setting the INC bit of Control Register 11 to '1'. The sequence always starts with Register 1, and ends with the register indexed by the REG[6:0] bits in Control Register 11.

Figure 9 shows the timing for the Auto-Increment Read operation. The operation begins by writing Control Register 11, setting INC to '1' and setting REG[6:0] to the last register to be read in the sequence. The actual Read opera-

tion starts on the next HIGH to LOW transition of the ML pin. The Read cycle starts by setting the R/W bit of the control word to '1', and setting all of the IDX[6:0] bits to '0.'. All subsequent bits input on the MDI are ignored while ML is set to '0.' For the first 8 clocks of the Read cycle, MDO is set to a high-impedance state. This is followed by a sequence of 8-bit words, each corresponding to the data contained in Control Registers 1 through N, where N is defined by the REG[6:0] bits in Control Register 11. The Read cycle is completed when ML is set to '1', immediately after the MC clock cycle for the least significant bit of Control Register N has completed.

CONTROL INTERFACE TIMING REQUIREMENTS

Figure 10 shows a detailed timing diagram for the Serial Control interface. Pay special attention to the setup and hold times, as well as t_{MLS} and t_{MLH} , which define minimum delays between edges of the ML and MC clocks. These timing parameters are critical for proper control port operation.

FIGURE 10. Control Interface Timing.

MODE CONTROL REGISTERS

User-Programmable Mode Controls

The PCM1604 includes a number of user-programmable functions which are accessed via control registers. The registers are programmed using the Serial Control Interface which was previously discussed in this data sheet. Table III lists the available mode control functions, along with their reset default conditions and associated register index.

Register Map

The mode control register map is shown in Table IV. Each register includes a R/W bit, which determines whether a register read (R/W =1) or write (R/W = 0) operation is performed. Each register also includes an index (or address) indicated by the IDX[6:0] bits.

FUNCTION	RESET DEFAULT	CONTROL REGISTER	INDEX, IDX[6:0]
Digital Attenuation Control, 0dB to -63dB in 0.5dB Steps	0dB, No Attenuation	1 through 6	01 _H - 07 _H
Digital Attenuation Load Control	Data Load Disabled	7	07 _H
Digital Attenuation Rate Select	2/f _S	7	07 _H
Soft Mute Control	Mute Disabled	7	07 _H
DAC 1-6 Operation Control	DAC 1-6 Enabled	8	08 _H
Infinite Zero Detect Mute	Disabled	8	08 _H
Audio Data Format Control	24-Bit Standard Format	9	09 _H

R/W Read/Write Mode Select

When R/W = 0, a Write operation is performed. When R/W = 1, a Read operation is performed. Default Value: 0

ATx[7:0] Digital Attenuation Level Setting

where x = 1-6, corresponding to the DAC output V_{OUT}x. These bits are Read/Write. Default Value: 1111 1111_B

Each DAC output, V_{OUT} 1 through V_{OUT} 6, has a digital attenuator associated with it. The attenuator may be set from 0dB to -63dB, in 0.5dB steps. Alternatively, the attenuator may be set to infinite attenuation (or mute).

The attenuation data for each channel can be set individually. However, the data load control (ATLD bit of Control Register 7) is common to all six attenuators. ATLD must be set to '1' in order to change an attenuator's setting. The attenuation level may be set using the formula below.

Attenuation Level (dB) = 0.5 (ATx [7:0]_{DEC} - 255)

where: ATx $[7:0]_{DEC} = 0$ through 255

for: ATx $[7:0]_{DEC} = 0$ through 128, the attenuator is set to infinite attenuation.

The following table shows attenuator levels for various settings.

ATx[7:0]	Decimal Value	Attenuator Level Setting	
1111 1111 _B	255	0dB, No Attenuation (default)	
1111 1110 _B	254	-0.5dB	
1111 1101 _B	253	-1.0dB	
•	•	•	
•	•	•

R/W Read/Write Mode Select

When R/W = 0, a Write operation is performed. When R/W = 1, a Read operation is performed. Default Value: 0

ATLD Attenuation Load Control

This bit is Read/Write. Default Value: 0

ATLD = 0	Attenuation Control Disabled (default)
ATLD = 1	Attenuation Control Enabled

The ATLD bit is used to enable loading of attenuation data set by registers 1 through 6. When ATLD = 0, the attenuation settings remain at the previously programmed level, ignoring new data loaded to registers 1 through 6. When ATLD = 1, attenuation data written to registers 1 through 6 is loaded normally.

ATTS Attenuation Rate Select

This bit is Read/Write. Default Value: 0

ATTS = 0	Attenuation rate is $2/f_{S}$ (default)
ATTS = 1	Attenuation rate is 4/f _S

Changes in attenuator levels are made by incrementing or decrementing the attenuator by one step (0.5dB) for every $2/f_S$ or $4/f_S$ time interval until the programmed attenuator setting is reached. This helps to minimize audible 'clicking', or zipper noise, while the attenuator is changing levels. The ATTS bit allows you to select the rate at which the attenuator is decremented/incremented during level transitions.

MUTx Soft Mute Control

where x = 1-6, corresponding to the DAC output $V_{OUT}x$. These bits are Read/Write. Default Value: 0

MUTx = 0	Mute Disabled (default)
MUTx = 1	Mute Enabled

The mute bits, MUT1 through MUT6, are used to enable or disable the Soft Mute function for the corresponding DAC outputs, V_{OUT} 1 through V_{OUT} 6. The Soft Mute function is incorporated into the digital attenuators. When Mute is disabled (MUTx = 0), the attenuator and DAC operate normally. When Mute is enabled by setting MUTx = 1, the digital attenuator for the corresponding output will be decremented from the current setting to the infinite attenuation setting one attenuator step (0.5dB) at a time, with the rate of change programmed by the ATTS bit. This provides a quiet, 'pop' free muting of the DAC output. Upon returning from Soft Mute, by setting MUTx = 0, the attenuator will be incremented one step at a time to the previously programmed attenuator level.

	-															
R/W	Read/Write Mode Select															
	When	R/W =	0, a W	rite op	eration	is per	formed									
	When $R/W = 1$, a Read operation is performed.															
	Default Value: 0															
INZD	Infinite Zero Detect Mute Control															
	This bi	it is Re	ad/Wri	te.												
	Defaul	t Value	e: 0													
	INZ	D = 0	Ι	nfinite	Zero I	Detect 1	Mute D	isabled	(defau	ult)						
	INZ	D = 1	I	nfinite	Zero I	Detect 1	Mute E	nabled								

The INZD bit is used to enable or disable the Zero Detect Mute function described in the Zero Flag and Infinite Zero Detect Mute section in this data sheet. The Zero Detect Mute function is independent of the Zero Flag output operation, so enabling or disabling the INZD bit has no effect on the Zero Flag outputs (ZERO1-ZERO6, ZEROA).

DACx DAC Operation Control

where x = 1-6, corresponding to the DAC output $V_{OUT}x$. These bits are Read/Write. Default Value: 0

DACx = 0	DAC Operation Enabled (default)
DACx = 1	DAC Operation Disabled

The DAC operation controls are used to enable and disable the DAC outputs, $V_{OUT}1$ through $V_{OUT}6$. When DACx = 0, the output amplifier input is connected to the DAC output. When DACx = 1, the output amplifier input is switched to the DC common-mode voltage ($V_{COM}1$ or $V_{COM}2$), equal to $V_{CC}/2$.

R/W Read/Write Mode Select

When R/W = 0, a Write operation is performed. When R/W = 1, a Read operation is performed. Default Value: 0

FLT0 Digital Filter Roll-Off Control

These bits are Read/Write. Default Value: 000_B

FLT0 = 0	Sharp Roll-Off (default)
FLT0 = 1	Slow Roll-Off

Bit FLT0 allows the user to select the digital filter roll-off that is best suited to their application. Two filter rolloff sections are available: Sharp or Slow. The filter responses for these selections are shown in the Typical Performance Curves section of this data sheet.

CLKD SCKO Frequency Selection

This bit is Read/Write. Default Value: 0

CLKD = 0	Full Rate, $f_{SCKO} = f_{SCKI}$ (default)
CLKD = 1	Half Rate, $f_{SCKO} = f_{SCKI}/2$

The CLKD bit is used to determine the clock frequency at the system clock output pin, SCKO.

CLKE SCKO Output Enable

This bit is Read/Write.

Default Value: 0

CLKE = 0	SCKO Enabled (default)
CLKE = 1	SCKO Disabled

The CLKE bit is used to enable or disable the system clock output pin, SCKO. When SCKO is enabled, it will output either a full or half rate clock, based upon the setting of the CLKD bit.

FMT[2:0] Audio Interface Data Format

These bits are Read/Write. Default Value: 000_B

FMT[2:0]	Audio Data Format Selection
000	24-Bit Standard Format, Right-Justified Data (default)
001	20-Bit Standard Format, Right-Justified Data
010	18-Bit Standard Format, Right-Justified Data
011	16-Bit Standard Format, Right-Justified Data
100	I ² S Format, 16- to 24-bits
101	Left-Justified Format, 16- to 24-Bits
110	Reserved
111	Reserved

The FMT[2:0] bits are used to select the data format for the serial audio interface.

R/W Read/Write Mode Select

When R/W = 0, a Write operation is performed. When R/W = 1, a Read operation is performed. Default Value: 0

INC Auto-Increment Read Control

This bit is Read/Write. Default Value: 0

INC = 0	Auto-Increment Read Disabled (default)
INC = 1	Auto-Increment Read Enabled

The INC bit is used to enable or disable the Auto-Increment Read feature of the Serial Control Interface. Refer to the Serial Control Interface section of this data sheet for details regarding Auto-Increment Read operation.

REG[6:0] Read Register Index

These bits are Read/Write.

Default Value: 01_H

Bits REG[6:0] are used to set the index of the register to be read when performing a Single Register Read operation. In the case of an Auto-Increment Read operation, bits REG[6:0] indicate the index of the last register to be read in the in the Auto-Increment Read sequence. For example, if Registers 1 through 6 are to be read during an Auto-Increment Read operation, bits REG[6:0] would be set to $06_{\rm H}$.

Refer to the Serial Control Interface section of this data sheet for details regarding the Single Register and Auto-Increment Read operations.

GPOx General Purpose Logic Output

Where: x = 1 through 6, corresponding to pins GPO1 through GPO6.

These bits are Read/Write.

Default Value: 0

GPOx = 0	Set GPOx to '0'.
GPOx = 1	Set GPOx to '1'.

The general-purpose output pins, GPO1 through GPO6, are enabled by setting GPOE = 1. These pins are used as general-purpose outputs for controlling user-defined logic functions. When general-purpose outputs are disabled (GPOE = 0), they default to the zero-flag function, ZERO1 through ZERO6.

GPOE General Purpose Output Enable

This bit is Read/Write. Default Value: 0

GPOE = 0	General-Purpose Outputs Disabled. Pins default to zero-flag function (ZERO1 through ZERO6).
GPOE = 1	General-Purpose Outputs Enabled. Data written to GPO1 through GPO6 will appear at the corresponding pins.

OVER Oversampling Rate Control

This bit is Read/Write.

Default Value: 0

OVER = 0	64x oversampling for $f_S \le$ 96kHz, and 32x oversampling for $f_S >$ 96kHz.
OVER = 1	128x oversampling for $f_S \le 96$ kHz, and 64x oversampling for $f_S > 96$ kHz.

The OVER bit is utilized to control the total oversampling performed by the D/A converter, including the digital interpolation filter and delta-sigma DAC. This is useful for controlling the D/A out-of-band noise spectrum, and designing a single, fixed value low-pass filter for use with all sampling frequencies.

ANALOG OUTPUTS

The PCM1604 includes six independent output channels, $V_{OUT}1$ through $V_{OUT}6$. These are unbalanced outputs, each capable of driving 3.1Vp-p typical into a 5k Ω AC load with V_{CC} = +5V. The internal output amplifiers for $V_{OUT}1$ through $V_{OUT}6$ are DC biased to the common-mode (or bipolar zero) voltage, equal to $V_{CC}/2$.

The output amplifiers include a RC continuous-time filter, which helps to reduce the out-of-band noise energy present at the DAC outputs due to the noise shaping characteristics of the PCM1604's delta-sigma D/A converters. The frequency response of this filter is shown in Figure 11. By itself, this filter is not enough to attenuate the out-of-band noise to an acceptable level for most applications. An external low-pass filter is required to provide sufficient outof-band noise rejection. Further discussion of DAC postfilter circuits is provided in the Applications Information section of this data sheet.

FIGURE 11. Output Filter Frequency Response.

V_{COM}1 AND V_{COM}2 OUTPUTS

Two unbuffered common-mode voltage output pins, $V_{COM}1$ (pin 16) and $V_{COM}2$ (pin 15), are brought out for decoupling purposes. These pins are nominally biased to a DC voltage level equal to $V_{CC}/2$. If these pins are to be used to bias external circuitry, a voltage follower is required for buffering purposes. Figure 12 shows an example of using the $V_{COM}1$ and $V_{COM}2$ pins for external biasing applications.

FIGURE 12. Biasing External Circuits Using the $V_{COM} \mathbf{1}$ and $V_{COM} \mathbf{2}$ Pins.

ZERO FLAG AND INFINITE ZERO DETECT MUTE FUNCTIONS

The PCM1604 includes circuitry for detecting an all '0' data condition for the data input pins, DATA1 through DATA3. This includes two independent functions: Zero Output Flags and Zero Detect Mute.

Although the flag and mute functions are independent of one another, the zero detection mechanism is common to both functions.

Zero Detect Condition

Zero Detection for each output channel is independent from the others. If the data for a given channel remains at a '0' level for 1024 sample periods (or LRCK clock periods), a Zero Detect condition exists for the that channel.

Zero Output Flags

Given that a Zero Detect condition exists for one or more channels, the Zero flag pins for those channels will be set to a logic '1'state. There are Zero Flag pins for each channel, ZERO1 through ZERO6 (pins 1 through 6). In addition, all six Zero Flags are logically ANDed together and the result provided at the ZEROA pin (pin 48), which is set to a logic '1' state when all channels indicate a zero detect condition. The Zero Flag pins can be used to operate external mute circuits, or used as status indicators for a microcontroller, audio signal processor, or other digitally controlled functions.

Infinite Zero Detect Mute

Infinite Zero Detect Mute is an internal logic function. The Zero Detect Mute can be enabled or disabled using the INZD bit of Control Register 8. The reset default is Zero Detect Mute disabled, INZD = 0. Given that a Zero Detect Condition exists for one or more channels, the zero mute circuitry will immediately force the corresponding DAC output(s) to the bipolar zero level, or $V_{CC}/2$. This is accomplished by switching the input of the DAC output amplifier from the delta-sigma modulator output to the DC common-mode reference voltage.

APPLICATIONS INFORMATION

CONNECTION DIAGRAMS

A basic connection diagram is shown in Figure 13, with the necessary power supply bypassing and decoupling components. Burr-Brown recommends using the component values shown in Figure 13 for all designs.

A typical application diagram is shown in Figure 14. Burr-Brown's REG1117-3.3 is used to generate +3.3V for V_{DD} from the +5V analog power supply. Burr-Brown's PLL1700E is used to generate the system clock input at SCKI, as well as generating the clock for the audio signal processor.

The use of series resistors $(22\Omega \text{ to } 100\Omega)$ are recommended for SCKI, LRCK, BCK, DATA1, DATA2, and DATA3. The series resistor combines with the stray PCB and device input capacitance to form a low-pass filter which removes high frequency noise from the digital signal, thus reducing high frequency emission

FIGURE 14. Typical Application Diagram.

POWER SUPPLIES AND GROUNDING

The PCM1604 requires a +5V analog supply and a +3.3V digital supply. The +5V supply is used to power the DAC analog and output filter circuitry, while the +3.3V supply is used to power the digital filter and serial interface circuitry. For best performance, the +3.3V supply should be derived from the +5V supply using a linear regulator, as shown in Figure 14.

Six capacitors are required for supply bypassing, as shown in Figure 13. These capacitors should be located as close as possible to the PCM1604 or PCM1605 package. The 10μ F capacitors should be tantalum or aluminum electrolytic, while the 0.1μ F capacitors are ceramic (X7R type is recommended for surface-mount applications).

D/A OUTPUT FILTER CIRCUITS

Delta-sigma D/A converters utilize noise shaping techniques to improve in-band Signal-to-Noise Ratio (SNR) performance at the expense of generating increased out-of-band noise above the Nyquist Frequency, or $f_S/2$. The out-of-band noise must be low-pass filtered in order to provide the optimal converter performance. This is accomplished by a combination of on-chip and external low-pass filtering.

Figures 15 and 16 show the recommended external low-pass active filter circuits for dual and single-supply applications. These circuits are 2nd-order Butterworth filters using the

Multiple Feedback (MFB) circuit arrangement, which reduces sensitivity to passive component variations over frequency and temperature. For more information regarding MFB active filter design, please refer to Burr-Brown Applications Bulletin AB-034, available from our web site (www.burr-brown.com) or your local Burr-Brown sales office.

Since the overall system performance is defined by the quality of the D/A converters and their associated analog output circuitry, high quality audio op amps are recommended for the active filters. Burr-Brown's OPA2134 and OPA2353 dual op amps are shown in Figures 15 and 16, and are recommended for use with the PCM1604 and PCM1605.

FIGURE 15. Dual Supply Filter Circuit.

FIGURE 16. Single-Supply Filter Circuit.

PCB LAYOUT GUIDELINES

A typical PCB floor plan for the PCM1604 and PCM1605 is shown in Figure 17. A ground plane is recommended, with the analog and digital sections being isolated from one another using a split or cut in the circuit board. The PCM1604 or PCM1605 should be oriented with the digital I/O pins facing the ground plane split/cut to allow for short, direct connections to the digital audio interface and control signals originating from the digital section of the board. Separate power supplies are recommended for the digital and analog sections of the board. This prevents the switching noise present on the digital supply from contaminating the analog power supply and degrading the dynamic performance of the D/A converters. In cases where a common +5V supply must be used for the analog and digital sections, an inductance (RF choke, ferrite bead) should be placed between the analog and digital +5V supply connections to avoid coupling of the digital switching noise into the analog circuitry. Figure 18 shows the recommended approach for single-supply applications.

FIGURE 17. Recommended PCB Layout.

FIGURE 18. Single-Supply PCB Layout.

THEORY OF OPERATION

The D/A converter section of the PCM1604 is based upon a multi-bit delta-sigma architecture. This architecture utilizes an 4th-order noise shaper and an 8-level quantizer, followed by an analog low-pass filter. A block diagram of the delta-sigma modulator is shown in Figure 19. This architecture has the advantage of stability and improved jitter tolerance when compared to traditional 1-bit (2-level) delta-sigma designs.

The combined oversampling rate of the digital interpolation filter and the delta-sigma modulator is 32fs, 64fs, or 128fs. The total oversampling rate is determined by the desired sampling frequency. If $fs \le 96$ kHz, then the OVER bit in Register 12 may be set to an oversampling rate to 64fs or 128fs. If fs > 96kHz, then the OVER bit may be used to set the oversampling rate to 32fs or 64fs. Figure 20 shows the outof- band quantization noise plots for both the 64x and 128x oversampling scenarios. Notice that the 128x oversampling plot shows significantly improved out-of-band noise performance, allowing for a simplified low-pass filter to be used at the output of the DAC. Figure 21 illustrates the simulated jitter sensitivity of the PCM1604. To achieve best performance, the system clock jitter should be less than 300 picoseconds. This is easily achieved using a quality clock generation IC, like Burr-Brown's PLL1700.

PERFORMANCE MEASUREMENTS

This section provides information on how to measure key dynamic performance parameters for the PCM1604 and PCM1605. In all cases, an Audio Precision System Two Cascade or equivalent audio measurement system is utilized to perform the testing.

TOTAL HARMONIC DISTORTION + NOISE

Total Harmonic Distortion + Noise (THD+N) is a significant figure of merit for audio D/A converters, since it takes into account both harmonic distortion and all noise sources within a specified measurement bandwidth. The true rms value of the distortion and noise is referred to as THD+N.

For the PCM1604 and PCM1605 D/A converters, THD+N is measured with a full scale, 1kHz digital sine wave as the test stimulus at the input of the DAC. The digital generator is set to 24-bit audio word length and a sampling frequency of 44.1kHz, or 96kHz. The digital generator output is taken from the unbalanced S/PDIF connector of the measurement system. The S/PDIF data is transmitted via coaxial cable to the digital audio receiver on the DEM-DAI1604 demo board. The receiver is then configured to output 24-bit data in either I²S or left-justified data format. The DAC audio interface format is programmed to match the receiver output format. The analog output is then taken from the DAC post filter and connected to the analog analyzer input of the measurment system. The analog input is band limited using filters resident in the analyzer. The resulting THD+N is measured by the analyzer and displayed by the measurement system.

FIGURE 22. Test Setup for THD+N Measurements.

DYNAMIC RANGE

Dynamic range is specified as A-Weighted, THD+N measured with a -60dBFS, 1kHz digital sine wave stimulus at the input of the D/A converter. This measurment is designed to give a good indicator of how the DAC will perform given a low-level input signal.

The measurement setup for the dynamic range measurement is shown in Figure 23, and is similar to the THD+N test setup discussed previously. The differences include the band limit filter selection, the additional A-Weighting filter, and the -60dBFS input level.

IDLE CHANNEL SIGNAL-TO-NOISE RATIO

The SNR test provides a measure of the noise floor of the D/A converter. The input to the D/A is all 0's data, and the D/A converter's Infinite Zero Detect Mute function must be disabled (default condition at power up for the PCM1604, PCM1605). This ensures that the delta-sigma modulator output is connected to the output amplifier circuit so that idle tones (if present) can be observed and effect the SNR measurement. The dither function of the digital generator must also be disabled to ensure an all '0's data stream at the input of the D/A converter.

The measurement setup for SNR is identical to that used for dynamic range, with the exception of the input signal level (see the notes provided in Figure 23).

FIGURE 23. Test Set-Up for Dynamic Range and SNR Meeasurements.

IMPORTANT NOTICE

Texas Instruments and its subsidiaries (TI) reserve the right to make changes to their products or to discontinue any product or service without notice, and advise customers to obtain the latest version of relevant information to verify, before placing orders, that information being relied on is current and complete. All products are sold subject to the terms and conditions of sale supplied at the time of order acknowledgment, including those pertaining to warranty, patent infringement, and limitation of liability.

TI warrants performance of its semiconductor products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

Customers are responsible for their applications using TI components.

In order to minimize risks associated with the customer's applications, adequate design and operating safeguards must be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance or customer product design.
