Preliminary Technical Data

FEATURES

Broadband RF, IF, and LO ports Conversion loss: 6 dB Noise figure: 6 dB High input IP3: 26 dBm High input P_{1dB}: 17 dBm Low LO drive level Single-ended design: no need for baluns Single-supply operation: 3 V @ 10 mA Miniature 8-lead 3 mm x 2 mm LFCSP package RoHS compliant

APPLICATIONS

Rev. PrC

Cellular base station Point-to-point radio links RF instrumentation

GENERAL DESCRIPTION

The ADL5350 is a high linearity, up-and-down converting mixer capable of operating over a broad input frequency range. It is well suited for demanding cellular base-station mixer designs that require high sensitivity and efficient blocker immunity. Based on a GaAs pHEMT single-ended mixer architecture, the ADL5350 provides excellent input linearity and low noise figure without the need for a high power level, local oscillator (LO) drive.

In 850 MHz/900 MHz receive applications, the ADL5350 provides a typical conversion loss of only 6 dB. The integrated LO amplifier allows a low LO drive level, typically only 4 dBm for most applications. The input IP3 is typically greater than 25 dBm, with an input compression point of 17 dBm. The high input linearity of the ADL5350 makes the device an excellent mixer for communications systems that require high blocker immunity, such as GSM 850/900 and 800 MHz CDMA2000. At 2 GHz, a slightly greater supply current is required to obtain similar performance.

For low frequency applications, the ADL5350 provides access to the gate contact of the output-mixing device. This allows an external LO coupling capacitor to be applied between the VPOS pin and GC pin, helping to improve the LO drive to the switching device. Using a single 100 pF capacitor allows high performance at the lower LO frequencies.

The single-ended broadband RF/IF port allows the device to be customized for a desired band of operation using simple external filter networks. The LO to RF isolation is based on the LO rejection of the RF port filter network. Greater isolation may be achieved using higher order filter networks as described in the Applications section of this data sheet.

The ADL5350 is fabricated on a GaAs pHEMT high performance IC process. The ADL5350 is available in a 3 mm \times 2 mm 8-lead LFCSP package. It operates over a -40°C to +85°C temperature range. An evaluation board is also available.

Information furnished by Analog Devices is believed to be accurate and reliable. However, no responsibility is assumed by Analog Devices for its use, nor for any infringements of patents or other rights of third parties that may result from its use. Specifications subject to change without notice. No license is granted by implication or otherwise under any patent or patent rights of Analog Devices.

ABSOLUTE MAXIMUM RATINGS

| Table 6. | |
|------------------------------|-----------------|
| Parameter | Rating |
| Supply Voltage, Vs | 6.0 V |
| RF Input Level | 20 dBm |
| LO Input Level | 20 dBm |
| Internal Power Dissipation | 324 mW |
| θ _{JA} | 154.3 °C/W |
| Maximum Junction Temperature | 135°C |
| Operating Temperature Range | -40°C to +85°C |
| Storage Temperature Range | –65°C to +150°C |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Table 7. Pin Function Descriptions

| Pin No. | Mnemonic | Function |
|---------|----------|---|
| 1, 8 | RF/IF | RF and IF Input/Output Ports. These nodes are internally tied together. RF and IF port separation is achieved using external tuning networks. |
| 2 | GND2 | Device Common (DC Ground) for RFIF Switching Circuitry. |
| 3 | LOIN | LO Input, AC-Coupled. |
| 4, 5 | GND1 | Device Common (DC Ground) for LO Buffer Circuitry. |
| 6 | VPOS | Positive Supply Voltage for the Drain of the LO Buffer. A series RF choke is needed on the supply line to provide proper ac-loading of the LO buffer amplifier. |
| 7 | GC | Gate Contact of Mixing Device. Typically not connected for high frequency mixing. Connecting capacitor between GC and VPOS permits low frequency applications. |

Figure 55. LO to IF Feedthrough vs. LO Frequency

FUNCTIONAL DESCRIPTION CIRCUIT DESCRIPTION

The ADL5350 is a GaAs MESFET, single-ended passive mixer with an integrated LO buffer amplifier. The device relies on the varying drain to source channel conductance of a FET junction to modulate an RF signal. A simplified schematic is shown in Figure 57.

The LO signal is applied to the gate contact of a FET-based buffer amplifier. The buffer amplifier provides sufficient gain of the LO signal to drive the resistive switch. Additionally, feedback circuitry provides the necessary bias to the FET buffer amplifier and RF/IF ports to achieve optimum modulation efficiency for common cellular frequencies. The GC node is the "gate-contact" of the RF/IF port resistive switch. The GC node enables external control of the bias level of the switching FET, allowing the user to override the internal bias generation circuitry, and allow further optimization of the mixer's dynamic performance at frequencies outside of the 800 MHz to 2000 MHz band.

The mixing of RF and LO signals is achieved by switching the channel conductance from the RF/IF port to ground at the rate of the LO. The RF signal is passed through an external bandpass network to help reject image bands and reduce the broadband noise presented to the mixer. The band-limited RF signal is presented to the time-varying load of the RF/IF port, which causes the envelope of the RF signal to be amplitude modulated at the rate of the LO. A filter network applied to the IF port is necessary to reject the RF signal and pass the wanted mixing product. In a down-conversion application, the IF filter network is designed to pass the difference frequency and present an open circuit to the incident RF frequency. Similarly, for an up-conversion application, the filter is designed to pass the sum frequency and reject the incident RF. As a result, the frequency response of the mixer is determined by the response characteristics of the external RF/IF filter networks.

IMPLEMENTATION PROCEDURE

The ADL5350 is a simple single-ended mixer that relies on offchip circuitry to achieve effective RF dynamic performance. The following steps should be followed to achieve optimum performance (see Figure 58 for component designations):

Figure 58. Reference Schematic

1. Tune LO buffer supply inductor for lowest supply current.

To start this procedure, it is necessary to provide an initial guess. Table 8 can be used as a starting point. It is not necessary to terminate or populate the RF and IF port networks to complete this first step. The RFIF pins can be left open while tuning the LO buffer networks.

Table 8. Recommended LO Bias Inductor

| Desired LO Frequency | Recommended LO Bias Inductor (L4) ¹ |
|----------------------|--|
| 380 MHz | 68 nH |
| 750 MHz | 24 nH |
| 1000 MHz | 18 nH |
| 1750 MHz | 3.8 nH |
| 2000 MHz | 2.1 nH |

¹The bias inductor should have a self-resonant frequency greater than the intended frequency of operation.

To test the supply current consumption, power up the device and apply the desired LO signal. Next, attempt to increase and decrease the LO frequency. If the current consumption increases as the LO frequency is decreased, then increase the value of L4. If the current consumption decreases as the LO frequency also decreases, then decrease the value of L4. After determining the optimum inductor value, the current consumption should be minimized at the desired LO frequency.

ADL5350

2. Tune the LO port input network for optimum return loss.

Typically, a bandpass network is used to pass the LO signal to the LOIN pin. It is desirable to block high frequency harmonics of the LO from the mixer core. LO harmonics cause higher RF frequency images to be down converted to the desired IF frequency, and result in a sensitivity degradation. If the intended LO source has poor harmonic distortion and spectral purity, it may be necessary to employ a higher order bandpass filter network. Figure 58 illustrates a simple L-C bandpass filter used to pass the fundamental frequency of the LO source. Capacitor C3 is a simple DC block, while the series-inductor (L3), along with the gate-to-source capacitance of the buffer amplifier, form a low-pass network. The native gate input of the LO buffer (FET) presents a rather high input impedance alone. The gate bias is generated internally using feedback that can result in a positive return loss at the intended LO frequency. If a better than -10 dB return loss is desired, it may be necessary to add shunt resistor to ground before the coupling capacitor (C3) to present a lower loading impedance to the LO source .

3. Design the RF and IF filter networks.

Figure 58 depicts simple LC tank filter networks for the IF and RF port interfaces. The RF port LC network is designed to pass the RF input signal. The series LC tank has a resonant frequency at $1/(2\pi\sqrt{LC})$. At resonance, the series reactances cancel, which presents a series short to the RF signal. A parallel LC tank is used on the IF port to reject the RF and LO signals. At resonance, the parallel LC tank presents an open circuit.

It is necessary to accommodate for the board parasitics, finite Q, and self-resonant frequencies of the LC components when designing the RF, IF, and LO filter networks. Table 9 provides suggested values for initial prototyping.

Table 9. Suggested RF, IF, and LO Filter Networks for Low-Side LO Injection

| RF Frequency | L1 ¹ | C1 | L2 | C2 | L3 | С3 | | |
|--------------|-----------------|--------|--------|--------|--------|--------|--|--|
| 450 MHz | 8.3 nH | 10 pF | 10 nH | 10 pF | 10 nH | 100 pF | | |
| 850 MHz | 6.8 nH | 4.7 pF | 4.7 nH | 5.6 pF | 8.2 nH | 100 pF | | |
| 1950 MHz | 1.7 nH | 1.5 pF | 1.7 nH | 1.2 pF | 3.5 nH | 100 pF | | |
| 2400 MHz | 0.67 nH | 1 pF | 1.5 nH | 0.7pF | 3.0 nH | 100 pF | | |

¹ The inductor should have a self-resonant frequency greater than the intended frequency of operation. L1 should be a high Q inductor for optimum NF performance.

APPLICATIONS LOW FREQUENCY APPLICATIONS

Using an external capacitor from the GC pin to VPOS makes it possible to operate the ADL5350 at frequencies below 100 MHz. This capacitor is required because the internal capacitor between the LO buffer and the gate of the device is only 4 pF. This capacitance combined with the gate resistance causes a high-pass filter corner of 80 MHz.

This high-pass filter corner decreases the LO energy that is reaching the mixer core. Using a 47 pF capacitor between VPOS and GC reduces this corner frequency to 7 MHz. The circuit in Figure 60 is designed for a RF of 70 MHz and an IF of 10.7 MHz. The LO is at 59.3 MHz (Low Side LO). The series resonant circuit is designed for 70 MHz and the parallel resonant circuit is designed for 65 MHz.

Figure 60. 70 MHz to 10.7 MHz Down-Conversion Schematic

70 MHz RECEIVE PERFORMANCE

 $V_s = 3 V$, $T_A = 25^{\circ}C$, LO power = 4 dBm, re: 50 Ω , unless otherwise noted.

HIGH FREQUENCY APPLICATIONS

The ADL5350 can be used at extended frequencies with some careful attention to board and component parasitics. Figure 61 is an example of a 2.3 GHz to 2.5 GHz down-conversion using a low-side LO. The performance of this circuit is depicted in Figure 62. Note that the inductor and capacitor values are very small, especially for the RF and IF ports. Above 2.5 GHz, it is necessary to consider alternate solutions to avoid unreasonably small inductor and capacitor values.

Figure 61. 2.3 GHz to 2.5 GHz Down-Conversion Schematic

The typical networks used for cellular applications below 2.5 GHz utilize band-select and band-reject networks on the RF and IF ports. At higher RF frequencies, these networks are not easily realized using lumped element components (discrete Ls and Cs). As a result, it is necessary to consider alternate filter network topologies to allow more reasonable values of inductors and capacitors.

Figure 63 depicts a cross-over filter network approach to provide isolation between the RF and IF ports for a downconverting application. The cross-over network essentially provides a high-pass filter to allow the RF signal to pass to the RF/IF node (Pin 1 and Pin 8), while presenting a low-pass filter, (which is actually band-pass when considering the DC blocking capacitor, C_{AC}). This allows the difference component ($f_{RF} - f_{LO}$) to be passed to the desired IF load.

Figure 63. 3.3 GHz to 3.8 GHz Down-Conversion Schematic

When designing the RF and IF port networks, it is important to remember that the networks share a common node (the RF/IF pins). In addition, the opposing network presents some loading impedance to the target network being designed. Classic audio crossover filter design techniques can be applied to help derive component values. However, some caution must be applied when selecting component values. At high RF frequencies, the board parasitics may significantly influence the final optimum inductor and capacitor component selections. Some empirical testing may be necessary to optimize the RF and IF port filter networks. The performance of the circuit depicted in Figure 63 is provided in Figure 64.

EVALUATION BOARD

An evaluation board is available for the ADL5350. The evaluation board has two halves: a low band designated as Board A, and a high band board designated as Board B. The schematic for the evaluation board is presented in Figure 65.

Table 12. Evaluation Board Configuration Options

| Component | Function | Default Conditions |
|-------------|---|---------------------------------------|
| C4-A, C4-B, | Supply Decoupling. C4-A and C4-B provide local bypassing of the supply. | C4-A = C4-B = 100 pF |
| С5-А, С5-В | C5-A and C5-B are used to filter the ripple of a noisy supply line. These are not always necessary. | C5-A = C5-B = 4.7 μF |
| L1-A, L1-B, | RF Input Network. | L1-A = 6.8 nH (0603CS from Coilcraft) |
| C1-A, C1-B | Designed to provide series resonance at the intended RF frequency. | L1-B = 1.7 nH (0302CS from Coilcraft) |
| | | C1-A = 4.7 pF, C1-B = 1.5 pF |
| L2-A, L2-B, | IF Output Network. | L2-A = 4.7 nH (0603CS from Coilcraft) |
| C2-A, C2-B, | Designed to provide parallel resonance at the geometric mean of the RF and LO | L2-B = 1.7 nH (0302CS from Coilcraft) |
| C6-A, C6-B | frequencies. | C2-A = 5.6 pF, C2-B = 1.2 pF |
| | | C6-A = C6-B = 1 nF |
| L3-A, L3-B, | LO Input Network. | L3-A = 8.2 nH (0603CS from Coilcraft) |
| СЗ-А, СЗ-В | Designed to block DC and optimize LO voltage swing | L3-B = 3.5 nH (0302CS from Coilcraft) |
| | at LOIN. | C3-A = C3-B = 100 pF |
| L4-A, L4-B | LO Buffer Amp Choke. | L4-A = 24 nH (0603CS from Coilcraft) |
| | Provides bias and ac loading impedance to LO buffer amp. | L4-B = 3.8 nH (0302CS from Coilcraft) |
