## FEATURES

$\pm 15$ kV ESD protection on receiver input pins 400 Mbps （ 200 MHz ）switching rates
Flow－through pin configuration simplifies PCB layout
150 ps channel－to－channel skew（typical）
100 ps differential skew（typical）
2.7 ns maximum propagation delay

3．3 V power supply
High impedance outputs on power－down
Low power design（ 3 mW quiescent typical）
Interoperable with existing 5 V LVDS drivers
Accepts small swing（ $\mathbf{3 1 0} \mathbf{~ m V}$ typical）differential input signal levels
Supports open，short，and terminated input fail－safe $\mathbf{0 V}$ to $\mathbf{- 1 0 0} \mathbf{~ m V}$ threshold region
Conforms to TIA／EIA－644 LVDS standard
Industrial operating temperature range of $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
Available in low profile TSSOP package

## APPLICATIONS

## Point－to－point data transmission

Multidrop buses
Clock distribution networks
Backplane receivers

## GENERAL DESCRIPTION

The ADN4668 is a quad－channel CMOS，low voltage differential signaling（LVDS）line receiver offering data rates of over 400 Mbps （ 200 MHz ）and ultralow power consumption．It features a flow－ through pin configuration for easy PCB layout and separation of input and output signals．
The device accepts low voltage（ 310 mV typical）differential input signals and converts them to a single－ended， 3 V TTL／CMOS logic level．

## FUNCTIONAL BLOCK DIAGRAM

Figure 1.

The ADN4668 also offers active－high and active－low enable／disable inputs（EN and $\overline{\mathrm{EN}}$ ）that control all four receivers．They disable the receivers and switch the outputs to a high impedance state．
This high impedance state allows the outputs of one or more ADN4668s to be multiplexed together and reduces the quies－ cent power consumption to 3 mW typical．
The ADN4668 and its companion driver，the ADN4667，offer a new solution to high speed，point－to－point data transmission and a low power alternative to emitter－coupled logic（ECL）or positive emitter－coupled logic（PECL）．

${ }^{1}$ Current-into-device pins are defined as positive. Current-out-of-device pins are defined as negative. All voltages are referenced to ground, unless otherwise specified.
${ }^{2}$ All typicals are given for $\mathrm{V}_{\mathrm{cc}}=3.3 \mathrm{~V}$ and $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$.
 common voltage range is 0.1 V to 2.3 V .
${ }^{4} \mathrm{~V}_{\text {CMR }}$ is reduced for larger $\mathrm{V}_{10}$. For example, if $\mathrm{V}_{10}=400 \mathrm{mV}, \mathrm{V}_{\text {CMR }}$ is 0.2 V to 2.2 V . The fail-safe condition with inputs shorted is not supported over the common-mode range of 0 V to 2.4 V but is supported only with inputs shorted and no external common-mode voltage applied. $\mathrm{V}_{10}$ up to $\mathrm{V}_{c c}-0 \mathrm{~V}$ can be applied to the $\mathrm{R}_{1 \times x+} / R_{1 N x}$ inputs with the common-mode voltage set to $V_{c c} / 2$. Propagation delay and differential pulse skew decrease when $V_{10}$ is increased from 200 mV to 400 mV . Skew specifications apply for $200 \mathrm{mV} \leq \mathrm{V}_{10} \leq 800 \mathrm{mV}$ over the common-mode range.
${ }^{5}$ Output short-circuit current (los) is specified as magnitude only; a minus sign indicates direction only. Only one output should be shorted at a time; do not exceed the maximum junction temperature specification.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 6. Pin Configuration
Table 4. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
| :---: | :---: | :---: |
| 1 | Rin1- | Receiver Channel 1 Inverting Input. When this input is more negative than Rin $1+$, Routi is high. When this input is more positive than $\mathrm{R}_{\mathrm{IN} 1+}$, $\mathrm{Rout1}_{1}$ is low. |
| 2 | Rin ${ }^{+}$ | Receiver Channel 1 Noninverting Input. When this input is more positive than $\mathrm{R}_{\mathrm{IN1}-,}$ Routi is high. When this input is more negative than Rin1-, Routı is low. |
| 3 | Rin2+ | Receiver Channel 2 Noninverting Input. When this input is more positive than $\mathrm{R}_{\mathrm{IN2} 2,}$ Routz is high. When this input is more negative than $\mathrm{R}_{\mathrm{IN2} 2}$, Rout2 is low. |
| 4 | RIN2- | Receiver Channel 2 Inverting Input. When this input is more negative than Rin2+, Routz is high. When this input is more positive than Rin2+, Rout2 is low. |
| 5 | Rin3- | Receiver Channel 3 Inverting Input. When this input is more negative than $\mathrm{R}_{\mathrm{IN} 3^{+},} \mathrm{Routs}^{\text {is }}$ high. When this input is more positive than $\mathrm{R}_{\mathrm{N} 3+}$, Routs is low. |
| 6 | Rin3+ | Receiver Channel 3 Noninverting Input. When this input is more positive than Rinз-, Routз is high. When this input is more negative than $\mathrm{R}_{\text {in3-, }}$ Rоит 3 is low. |
| 7 | Rin4+ | Receiver Channel 4 Noninverting Input. When this input is more positive than RiN4-, Routa is high. When this input is more negative than Rin4-, Routa is low. |
| 8 | Rin4- | Receiver Channel 4 Inverting Input. When this input is more negative than RIN4t, Routa is high. When this input is more positive than Rinat, Routs is low. |
| 9 | $\overline{\mathrm{EN}}$ | Active-Low Enable and Power-Down Input with Pulldown ( 3 V TTL/CMOS). When EN is held high, $\overline{\mathrm{EN}}$ enables the receiver outputs when $\overline{\mathrm{EN}}$ is low or open circuit and puts the receiver outputs into a high impedance state and powers down the device when $\overline{\mathrm{EN}}$ is high. |
| 10 | Routa | Receiver Channel 4 Output ( $3 \mathrm{~V} \mathrm{TL} / \mathrm{CMOS}$ ). If the differential input voltage between RiN4+ and RiN4- is positive, this output is high. If the differential input voltage is negative, this output is low. |
| 11 | Routs | Receiver Channel 3 Output ( $3 \mathrm{~V} \mathrm{TL} / \mathrm{CMOS}$ ). If the differential input voltage between Rin3+ and Rin3- is positive, this output is high. If the differential input voltage is negative, this output is low. |
| 12 | GND | Ground Reference Point for All Circuitry on the Part. |
| 13 | Vcc | Power Supply Input. These parts can be operated from 3.0 V to 3.6 V . |
| 14 | Rout2 | Receiver Channel 2 Output ( $3 \mathrm{~V} T \mathrm{TL} / \mathrm{CMOS}$ ). If the differential input voltage between $\mathrm{R}_{\mathrm{IN2}}$ and $\mathrm{R}_{\mathrm{IN} 2-}$ is positive, this output is high. If the differential input voltage is negative, this output is low. |
| 15 | Rout1 | Receiver Channel 1 Output ( $3 \mathrm{~V} \mathrm{TL} / \mathrm{CMOS}$ ). If the differential input voltage between Rin1+ and Rin 1 - is positive, this output is high. If the differential input voltage is negative, this output is low. |
| 16 | EN | Active-High Enable and Power-Down Input ( $3 \mathrm{~V} \mathrm{TL} / \mathrm{CMOS}$ ). When $\overline{\mathrm{EN}}$ is held low or open circuit, EN enables the receiver outputs when EN is high and puts the receiver outputs into a high impedance state and powers down the device when EN is low. |

## ADN4668

## THEORY OF OPERATION

The ADN4668 is a quad-channel line receiver for low voltage differential signaling. It takes a differential input signal of 310 mV typical and converts it into a single-ended 3 V TTL/CMOS logic signal.

A differential current input signal, received via a transmission medium such as a twisted pair cable, develops a voltage across a terminating resistor, $\mathrm{R}_{\mathrm{T}}$. This resistor is chosen to match the characteristic impedance of the medium, typically around $100 \Omega$. The differential voltage is detected by the receiver and converted back into a single-ended logic signal.

When the noninverting receiver input, $\mathrm{R}_{\mathrm{IN}_{\mathrm{X}+}}$, is positive with respect to the inverting input, $\mathrm{R}_{\mathrm{INX}^{-}}$(current flows through $\mathrm{R}_{\mathrm{T}}$ from $\mathrm{R}_{\mathbb{N X}_{\mathrm{x}}}$ to $\mathrm{R}_{\mathrm{N}_{\mathrm{N} x}-}$ ), Routx is high. When the noninverting receiver input, $\mathrm{R}_{\mathrm{IN}+}$, is negative with respect to the inverting input, $\mathrm{R}_{\mathrm{INx}-}$ (current flows through $\mathrm{R}_{\mathrm{T}}$ from $\mathrm{R}_{\mathrm{INx}-}$ to $\mathrm{R}_{\mathrm{IN} \mathrm{x}+}$ ), $\mathrm{R}_{\text {out }}$ is low.
Using the ADN4667 as a driver, the received differential current is between $\pm 2.5 \mathrm{~mA}$ and $\pm 4.5 \mathrm{~mA}$ ( $\pm 3.1 \mathrm{~mA}$ typical), developing between $\pm 250 \mathrm{mV}$ and $\pm 450 \mathrm{mV}$ across a $100 \Omega$ termination resistor. The received voltage is centered around the receiver offset of 1.2 V . In other words, the noninverting receiver input is typically $(1.2 \mathrm{~V}+[310 \mathrm{mV} / 2])=1.355 \mathrm{~V}$, and the inverting receiver input is $(1.2 \mathrm{~V}-[310 \mathrm{mV} / 2])=1.045 \mathrm{~V}$ for Logic 1 . For Logic 0 , the inverting and noninverting input voltages are reversed. Note that because the differential voltage reverses polarity, the peak-to-peak voltage swing across $\mathrm{R}_{\mathrm{T}}$ is twice the differential voltage.
Current-mode signaling offers considerable advantages over voltage-mode signaling, such as the RS-422. The operating
current remains fairly constant with increased switching frequency, whereas the operating current of voltage-mode drivers increases exponentially in most cases. This increase is
caused by the overlap as internal gates switch between high and low, causing currents to flow from $V_{C C}$ to ground. A current-mode device reverses a constant current between its two outputs, with no significant overlap currents.
This is similar to emitter-coupled logic (ECL) and positive emittercoupled logic (PECL), but without the high quiescent current of ECL and PECL.

## ENABLE INPUTS

The ADN4668 has active-high and active-low enable inputs that put all the logic outputs into a high impedance state when disabled, reducing device current consumption from 9 mA typical to 1 mA typical. See Table 5 for a truth table of the enable inputs.

Table 5. Enable Inputs Truth Table

| EN | $\overline{\mathbf{E N}}$ | $\mathbf{R}_{\mathbf{N N}_{\mathrm{x}+}}$ | $\mathbf{R}_{\mathbf{N} \mathbf{x}-}$ | Routx |
| :--- | :--- | :--- | :--- | :--- |
| High | Low or Open | 1.045 V | 1.355 V | 0 |
| High | Low or Open | 1.355 V | 1.045 V | 1 |
| Any other combination <br> of EN and $\overline{\mathrm{EN}}$ | X | X | High-Z |  |

## APPLICATIONS INFORMATION

Figure 22 shows a typical application for point-to-point data transmission using the ADN4667 as the driver and the ADN4668 as the receiver.
