## 70MHz/1mA Current Mode Feedback Amplifiers

## élantec

The EL2270 is a dual current-feedback operational amplifiers which achieves a -3 dB bandwidth of 70 MHz at a gain of +1 while consuming only 1 mA of supply current per amplifier. It will operate with dual supplies ranging from $\pm 1.5 \mathrm{~V}$ to $\pm 6 \mathrm{~V}$, or from single supplies ranging from +3 V to +12 V . In spite of its low supply current, the EL2270 can output 55 mA while swinging to $\pm 4 \mathrm{~V}$ on $\pm 5 \mathrm{~V}$ supplies. These attributes make the EL2270 an excellent choice for low power and/or low voltage cable-driver, HDSL, or RGB applications.

For applications where board space is extremely critical. The EL2270 is available in industry standard pinouts in SO package.

For single and dual applications with disable, consider the EL2176 (8-pin single) or EL2276 (14-pin dual). For higher speed applications where power is still a concern, consider the EL2180/EL2186 family which also comes in similar single, dual, triple and quad configurations. The EL2180/EL2186 family provides a -3dB bandwidth of 250 MHz while consuming 3 mA of supply current per amplifier.

## Ordering Information

NOTE: Intersil Pb-free products employ special Pb-free material sets; molding compounds/die attach materials and $100 \%$ matte tin plate termination finish, which is compatible with both SnPb and Pb -free soldering operations. Intersil Pb -free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb -free requirements of IPC/JEDEC J Std-020B.

## Features

- Dual topologies
- 1 mA supply current (per amplifier)
- $70 \mathrm{MHz}-3 \mathrm{~dB}$ bandwidth
- Low cost
- Single- and dual-supply operation down to $\pm 1.5 \mathrm{~V}$
- $0.15 \% / 0.15^{\circ}$ diff. gain/diff. phase into $150 \Omega$
- $800 \mathrm{~V} / \mathrm{\mu s}$ slew rate
- Large output drive current - 55 mA
- Also available with disable in single (EL2176) \& dual (EL2276)
- Higher speed EL2180/EL2186 family available ( $3 \mathrm{~mA} / 250 \mathrm{MHz}$ ) in single, dual, and quad
- Pb-free available

## Applications

- Low power/battery applications
- HDSL amplifiers
- Video amplifiers
- Cable drivers
- RGB amplifiers
- Test equipment amplifiers
- Current to voltage converters

## Pinout

## Applications Information

## Product Description

The EL2270 is a current-feedback operational amplifier that offers a wide -3 dB bandwidth of 70 MHz and a low supply current of 1 mA per amplifier. This product also features high output current drive. The EL2270 can output 55 mA per amplifier and works with supply voltages ranging from a single 3 V to $\pm 6 \mathrm{~V}$, and is also capable of swinging to within 1 V of either supply on the input and the output. Because of its current-feedback topology, the EL2270 does not have the normal gain-bandwidth product associated with voltagefeedback operational amplifiers. This allows its -3dB bandwidth to remain relatively constant as closed-loop gain is increased. This combination of high bandwidth and low power, together with aggressive pricing make the EL2270 the ideal choice for many low-power/high-bandwidth applications such as portable computing, HDSL, and video processing.

For applications where board space is extremely critical. The EL2270 is available in industry standard pinouts in SO package.

For single and dual applications with disable, consider the EL2176 (8-pin single) and EL2276 (14-pin dual). If higher speed is required, refer to the EL2180/EL2186 family which provides singles, duals, triples, and quads with 250 MHz of bandwidth while consuming 3 mA of supply current per amplifier.

## Power Supply Bypassing and Printed Circuit Board Layout

As with any high-frequency device, good printed circuit board layout is necessary for optimum performance. Ground plane construction is highly recommended. Lead lengths should be as short as possible. The power supply pins must be well bypassed to reduce the risk of oscillation. The combination of a $4.7 \mu \mathrm{~F}$ tantalum capacitor in parallel with a $0.1 \mu \mathrm{~F}$ capacitor has been shown to work well when placed at each supply pin.

For good AC performance, parasitic capacitance should be kept to a minimum especially at the inverting input (see the Capacitance at the Inverting Input section). Ground plane construction should be used, but it should be removed from the area near the inverting input to minimize any stray capacitance at that node. Carbon or Metal-Film resistors are acceptable with the Metal-Film resistors giving slightly less peaking and bandwidth because of their additional series inductance. Use of sockets, particularly for the SO package should be avoided if possible. Sockets add parasitic inductance and capacitance which will result in some additional peaking and overshoot.

## Capacitance at the Inverting Input

Any manufacturer's high-speed voltage- or current-feedback amplifier can be affected by stray capacitance at the
inverting input. For inverting gains this parasitic capacitance has little effect because the inverting input is a virtual ground, but for non-inverting gains this capacitance (in conjunction with the feedback and gain resistors) creates a pole in the feedback path of the amplifier. This pole, if low enough in frequency, has the same destabilizing effect as a zero in the forward open-loop response. The use of large value feedback and gain resistors further exacerbates the problem by further lowering the pole frequency.

The experienced user with a large amount of PC board layout experience may find in rare cases that the EL2270 has less bandwidth than expected. The reduction of feedback resistor values (or the addition of a very small amount of external capacitance at the inverting input, e.g. 0.5 pF ) will increase bandwidth as desired. Please see the curves for Frequency Response for Various $R_{F}$ and $R_{G}$, and Frequency Response for Various $\mathrm{C}_{\mathrm{IN}}-$.

## Feedback Resistor Values

The EL2270 has been designed and specified at gains of +1 and +2 with $R_{F}=1 \mathrm{k} \Omega$. This value of feedback resistor gives 70 MHz of -3 dB bandwidth at $A_{V}=+1$ with about 1.5 dB of peaking, and 60 MHz of -3 dB bandwidth at $A_{V}=+2$ with about 0.5 dB of peaking. Since the EL2270 is a currentfeedback amplifier, it is also possible to change the value of $R_{F}$ to get more bandwidth. As seen in the curve of Frequency Response For Various $R_{F}$ and $R_{G}$, bandwidth and peaking can be easily modified by varying the value of the feedback resistor.

Because the EL2270 is a current-feedback amplifier, its gainbandwidth product is not a constant for different closed-loop gains. This feature actually allows the EL2270 to maintain about the same -3dB bandwidth, regardless of closed-loop gain. However, as closed-loop gain is increased, bandwidth decreases slightly while stability increases. Since the loop stability is improving with higher closed-loop gains, it becomes possible to reduce the value of $R_{F}$ below the specified $1 \mathrm{k} \Omega$ and still retain stability, resulting in only a slight loss of bandwidth with increased closed-loop gain.

## Supply Voltage Range and Single-Supply Operation

The EL2270 has been designed to operate with supply voltages having a span of greater than 3 V , and less than 12V. In practical terms, this means that the EL2270 will operate on dual supplies ranging from $\pm 1.5 \mathrm{~V}$ to $\pm 6 \mathrm{~V}$. With a single-supply, the EL2270 will operate from +3 V to +12 V .

As supply voltages continue to decrease, it becomes necessary to provide input and output voltage ranges that can get as close as possible to the supply voltages. The EL2270 has an input voltage range that extends to within 1V of either supply. So, for example, on a single +5 V supply, the EL2270 has an input range which spans from 1V to 4V. The output range of the EL2270 is also quite large, extending to within 1 V of the supply rail. On a $\pm 5 \mathrm{~V}$ supply, the output is
therefore capable of swinging from -4 V to +4 V . Single-supply output range is even larger because of the increased negative swing due to the external pull-down resistor to ground. On a single +5 V supply, output voltage range is about 0.3 V to 4 V .

## Video Performance

For good video performance, an amplifier is required to maintain the same output impedance and the same frequency response as DC levels are changed at the output. This is especially difficult when driving a standard video load of $150 \Omega$, because of the change in output current with DC level. Until the EL2270, good Differential Gain could only be achieved by running high idle currents through the output transistors (to reduce variations in output impedance). These currents were typically more than the entire 1 mA supply current of each EL2270 amplifier! Special circuitry has been incorporated in the EL2270 to reduce the variation of output impedance with current output. This results in dG and dP specifications of $0.15 \%$ and $0.15^{\circ}$ while driving $150 \Omega$ at a gain of +2 .

Video performance has also been measured with a $500 \Omega$ load at a gain of +1 . Under these conditions, the EL2270 has dG and dP specifications of $0.01 \%$ and $0.02^{\circ}$ respectively while driving $500 \Omega$ at $A_{V}=+1$.

## Output Drive Capability

In spite of its low 1 mA of supply current, each amplifier of the EL2270 is capable of providing a minimum of $\pm 50 \mathrm{~mA}$. These output drive levels are unprecedented in amplifiers running at these supply currents. With a minimum $\pm 80 \mathrm{~mA}$ of output drive, the $\pm 50 \mathrm{~mA}$ minimum output drive of each EL2270 amplifier allows swings of $\pm 2.5 \mathrm{~V}$ into $50 \Omega$ loads.

## Driving Cables and Capacitive Loads

When used as a cable driver, double termination is always recommended for reflection-free performance. For those applications, the back-termination series resistor will decouple the EL2270 from the cable and allow extensive capacitive drive. However, other applications may have high capacitive loads without a back-termination resistor. In these applications, a small series resistor (usually between $5 \Omega$ and $50 \Omega$ ) can be placed in series with the output to eliminate most peaking. The gain resistor $\left(\mathrm{R}_{\mathrm{G}}\right)$ can then be chosen to make up for any gain loss which may be created by this additional resistor at the output. In many cases it is also possible to simply increase the value of the feedback resistor $\left(R_{F}\right)$ to reduce the peaking.

## Current Limiting

The EL2270 has no internal current-limiting circuitry. If any output is shorted, it is possible to exceed the Absolute Maximum Ratings for output current or power dissipation, potentially resulting in the destruction of the device.

## Power Dissipation

With the high output drive capability of the EL2270, it is possible to exceed the $150^{\circ} \mathrm{C}$ Absolute Maximum junction temperature under certain very high load current conditions. Generally speaking, when $R_{L}$ falls below about $25 \Omega$, it is important to calculate the maximum junction temperature (TJMAX) for the application to determine if power-supply voltages, load conditions, or package type need to be modified for the EL2270 to remain in the safe operating area. These parameters are calculated as follows [1]:
$T_{J M A X}=T_{M A X}+\left(\Theta_{J A} \times n \times P D_{M A X}\right)$
where:
$\mathrm{T}_{\text {MAX }}=$ Maximum ambient temperature
$\theta_{\mathrm{JA}}=$ Thermal resistance of the package
$\mathrm{n}=$ Number of amplifiers in the package
$\mathrm{PD}_{\mathrm{MAX}}=$ Maximum power dissipation of each amplifier in the package

PD ${ }_{\text {MAX }}$ for each amplifier can be calculated as follows [2]:
$P D_{\text {MAX }}=\left(2 \times V_{S} \times I_{\text {SMAX }}\right)+\left(V_{S}-V_{\text {OUTMAX }}\right) \times \frac{\mathrm{V}_{\text {OUTMAX }}}{R_{\mathrm{L}}}$
where:
$\mathrm{V}_{\mathrm{S}}=$ Supply voltage
ISMAX = Maximum supply current of 1 amplifier
$V_{\text {OUTMAX }}=$ Maximum output voltage of the application
$R_{L}=$ Load resistance
