Description

The FS6X-Series is specially designed for off-line DC-DC converters with minimal external components. This device combines a current mode PWM controller with a high voltage power SenseFET in a single package. The PWM controller includes integrated fixed frequency oscillator, line under voltage lockout, sleep on/off function, thermal shutdown protection, over voltage protection, pulse-by-pulse current limit, and temperature compensated precise current sources for a loop compensation. Compared with the discrete MOSFET and PWM controller solution, the FS6X-Series can reduce total cost, component count, size, and weight, while simultaneously increasing efficiency, productivity, and system reliability.

Pin Definitions

Pin Number	Pin Name	Pin Function Description
1	Drain	This pin is the high voltage power SenseFET drain connection.
2	GND	This pin is the control ground and the SenseFET source.
3	Vcc	This pin is the positive supply input. This pin provides internal operating current for both start-up and steady-state operation.
4	Feedback (FB)	This pin is internally connected to the inverting input of the PWM comparator. The collector of an opto-coupler is typically tied to this pin. For stable operation, a capacitor should be placed between this pin and GND. If the voltage of this pin reaches 7.5V, the over load protection is activated resulting in shutdown of the IC.
5	N.C.	This pin is not connected.
6	Line Sense (LS)	According to the voltage of this pin, three operation modes are defined: normal operation mode, line under voltage lock out mode, and sleep mode. If the voltage of this pin is smaller than 2.55V, the IC goes into the line under voltage lock out, stopping switching operation. If the voltage of this pin is smaller than 1.8V, the IC enters into sleep mode. During sleep mode, reference voltage generation circuit including the shunt regulator is disabled and only 300uA operation current is required.

Applications Information

1. Startup

To guarantee stable operation of the control IC, Vcc has under voltage lockout (UVLO) with 6V hysteresis. Figure 16 shows the relation between the supply current (Icc) and the supply voltage (Vcc). Before Vcc reaches 15V, the start-up current is 60μA, which is usually provided by the DC link through start-up resistor. When Vcc reaches 15V, the control IC begins operation and the operating current increases to 10mA as shown. Once the control IC starts operation, it continues its normal operation unless Vcc goes below the stop voltage of 9V.

Figure 16. Relation between Supply Current and Voltage

2. Feedback Control

The FS6X-Series employs current mode control. The voltage of the feedback pin is compared with the current sense voltage for pulse width modulation (PWM). Figure 17 illustrates the simplified PWM block. The feedback voltage determines the peak drain current of the SenseFET. Usually, an opto-coupler, along with the TL431(shunt regulator) are used to implement the feedback network. The collector of the opto-coupler transistor is connected to the feedback pin and the emitter is connected to the ground pin. When the voltage of the reference pin of the TL431 exceeds the internal reference voltage of 2.5V, the opto-coupler diode current increases, pulling down the feedback voltage.

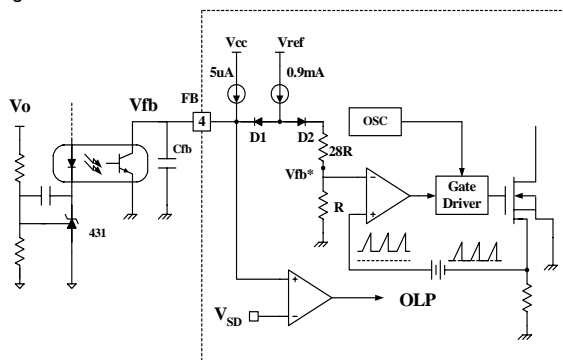

Figure 17. Pulse Width Modulation (PWM) Circuit

3. Protection Circuit

Besides pulse-by-pulse current limit, the FS6X-Series has the following self protection functions: over load protection (OLP), over voltage protection (OVP), and thermal shutdown (TSD). Because these protection circuits are fully integrated into the IC without external components, the reliability is improved. In the event of a fault condition, FS6X-Series enters into auto-restart operation. Once the fault condition occurs, switching operation is terminated, and the MOSFET remains off, which causes Vcc to be reduced. When Vcc reaches 9V, the protection is reset and the supply current reduces to 60uA. Then, Vcc begin to increase with the current provided through the start-up resistor. When Vcc reaches 15V, FS6X-Series resumes its normal operation if the fault condition is removed. In this manner, the auto-restart alternately enables and disables the switching of the power MOSFET until the fault condition is eliminated as illustrated in Figure 18.

Figure 18. Auto Restart Operation After Protection

3.1 Pulse-by-pulse Current Limit

As shown in Figure 17, the drain current of the power MOSFET is limited by the inverting input of PWM comparator (Vfb*). Assuming that the 0.9mA current source flows only through the internal resistor (28R +R= 2.9k), the cathode voltage of diode D2 is about 2.6V. Since D1 is blocked when the feedback voltage (Vfb) exceeds 2.6V, the maximum voltage of the cathode of D2 is 2.6V. Therefore, the maximum value of Vfb* is about 0.1V, which limits the peak value of the power MOSFET drain current.

3.2 Over Load Protection (OLP)

Overload means that the load current exceeds a pre-set level due to an abnormal situation. In this situation, the protection circuit should be activated to protect the SMPS (Switch Mode Power Supplies). However, even when the SMPS is in normal operation, the over load protection circuit can be activated during the load transition. To avoid this undesired operation, the over load protection circuit is designed to be activated after a specified period to determine whether it is a transient situation or an overload situation. Because of the pulse-by-pulse current limit capability, the maximum peak current through the SMPS is limited, and therefore the maximum input power is restricted with a given input voltage. If the output consumes beyond this maximum power, the output voltage (Vo) decreases below the set voltage. This reduces the current through the opto-coupler diode which also reduces opto-coupler transistor current increasing Vfb. If Vfb exceeds 2.6V, D1 is blocked and the 5mA current source starts to charge Cfb slowly compared to when the 0.9mA current source charges Cfb. In this condition, Vfb continues increasing until it reaches 7.5V, and the switching operation is terminated at that time as shown in Figure 19. The delay time for shutdown is the time required to charge Cfb from 2.6V to 7.5V with 5mA. When Cfb is 10nF (103), T12 is approximately 9.8ms and when Cfb is 0.1mF (104), T12 is approximately 98ms. These values are enough to prevent SMPS from being shut down during transient situations.

Figure 19. Over Load Protection

3.3 Over Voltage Protection (OVP)

In the case of a malfunction in the secondary side feedback circuit, or feedback loop open caused by a defect of solder, the current through the opto-coupler transistor becomes almost zero. Then, Vfb climbs up in a similar manner to the over load situation, forcing the preset maximum current to be supplied to the secondary side until the over load protection is activated. Because more than required energy is provided to the output, the output voltage may exceed the rated voltage before the over load protection is activated, resulting in the breakdown of the devices in the secondary side. To prevent this situation, an over voltage protection (OVP) circuit is employed. In general, Vcc is proportional to the output voltage and FS6X-Series uses Vcc instead of directly monitoring the output voltage. If VCC exceeds 25V, OVP circuit is activated resulting in termination of

switching. To avoid undesired activation of OVP during normal operation, Vcc should be properly designed to be below 25V.

3.4 Thermal Shutdown (TSD)

The thermal shutdown circuitry senses the junction temperature. The threshold is set at 160×C. When the junction temperature rises above this threshold (160×C), the power MOSFET is disabled.

4. Line UVLO and Sleep Mode

According to the voltage of the Line Sense pin, three operation modes are defined: normal operation mode, line under voltage lock out mode, and sleep mode, as shown in Figure 20. When the voltage of this pin is over 2.55V, FS6X-Series operates in normal mode. When the voltage of this pin is less than 2.55V, it goes into line under voltage lock out mode terminating switching operation. When the voltage of this pin is less than 1.8V, it enters into sleep mode. During sleep mode, the reference voltage generation circuit, including the shunt regulator, is disabled and only 300mA operation current is required.
