2.7 V TO 5.5 V LOW POWER 8-BIT DIGITAL-TO-ANALOG CONVERTERS WITH POWER DOWN

SLAS231 – JUNE 1999

- **8-Bit Voltage Output DAC**
- **Programmable Settling Time vs Power Consumption**
 - 3 μ s in Fast Mode
 - 9 μ s in Slow Mode
- **Ultra Low Power Consumption:**
 - 900 μ W Typ in Slow Mode at 3 V
 - 2.1 mW Typ in Fast Mode at 3 V
- **Differential Nonlinearity . . . <0.2 LSB Typ**
- **Compatible With TMS320 and SPI Serial Ports**
- **Power-Down Mode**

- **Buffered High-Impedance Reference Input**
- **Monotonic Over Temperature**
- **Available in MSOP Package**

applications

- Digital Servo Control Loops
- Digital Offset and Gain Adjustment
- Industrial Process Control
- Machine and Motion Control Devices
- Mass Storage Devices

description

The TLV5623 is a 8-bit voltage output digital-to-analog converter (DAC) with a flexible 4-wire serial interface. The 4-wire serial interface allows glueless interface to TMS320, SPI, QSPI, and Microwire serial ports. The TLV5623 is programmed with a 16-bit serial string containing 4 control and 12 data bits. Developed for a wide range of supply voltages, the TLV5623 can operate from 2.7 V to 5.5 V.

The resistor string output voltage is buffered by a x2 gain rail-to-rail output buffer. The buffer features a Class AB output stage to improve stability and reduce settling time. The settling time of the DAC is programmable to allow the designer to optimize speed versus power dissipation. The settling time is chosen by the control bits within the 16-bit serial input string. A high-impedance buffer is integrated on the REFIN terminal to reduce the need for a low source impedance drive to the terminal.

Implemented with a CMOS process, the TLV5623 is designed for single supply operation from 2.7 V to 5.5 V. The device is available in an 8-terminal SOIC package. The TLV5623C is characterized for operation from 0°C to 70°C. The TLV5623I is characterized for operation from –40°C to 85°C.

APPLICATION INFORMATION

general function

The TLV5623 is an 8-bit single supply DAC based on a resistor string architecture. The device consists of a serial interface, speed and power-down control logic, a reference input buffer, a resistor string, and a rail-to-rail output buffer.

The output voltage (full scale determined by external reference) is given by:

$$2 \text{ REF } \frac{\text{CODE}}{0x1000} \text{ [V]}$$

Where REF is the reference voltage and CODE is the digital input value within the range of 0x000 to 0xFF0. Bits 3 to 0 must be set to zero. A power-on reset initially resets the internal latches to a defined state (all bits zero).

serial interface

The device has to be enabled with $\overline{\text{CS}}$ set to low. A falling edge of FS starts shifting the data bit-per-bit (starting with the MSB) to the internal register on the falling edges of SCLK. After 16 bits have been transferred or FS rises, the content of the shift register is moved to the DAC latch, which updates the voltage output to the new level.

The serial interface of the TLV5623 can be used in two basic modes:

- Four wire (with chip select)
- Three wire (without chip select)

Using chip select (four-wire mode), it is possible to have more than one device connected to the serial port of the data source (DSP or microcontroller). The interface is compatible with the TMS320 family. Figure 15 shows an example with two TLV5623s connected directly to a TMS320 DSP.

Figure 15. TMS320 Interface

TLV5623C, TLV5623I

2.7 V TO 5.5 V LOW POWER 8-BIT DIGITAL-TO-ANALOG CONVERTERS WITH POWER DOWN

SLAS231 – JUNE 1999

APPLICATION INFORMATION

serial interface (continued)

If there is no need to have more than one device on the serial bus, then $\overline{\text{CS}}$ can be tied low. Figure 16 shows an example of how to connect the TLV5623 to a TMS320, SPI, or Microwire port using only three pins.

Figure 16. Three-Wire Interface

Notes on SPI and Microwire: Before the controller starts the data transfer, the software has to generate a falling edge on the I/O pin connected to FS. If the word width is 8 bits (SPI and Microwire), two write operations must be performed to program the TLV5623. After the write operation(s), the DAC output is updated automatically on the sixteenth positive clock edge.

serial clock frequency and update rate

The maximum serial clock frequency is given by:

$$f_{\text{SCLKmax}} = \frac{1}{t_{\text{wH(min)}} + t_{\text{wL(min)}}} = 20 \text{ MHz}$$

The maximum update rate is:

$$f_{\text{UPDATEmax}} = \frac{1}{16 (t_{\text{wH(min)}} + t_{\text{wL(min)}})} = 1.25 \text{ MHz}$$

The maximum update rate is a theoretical value for the serial interface, since the settling time of the TLV5623 has to be considered also.

data format

The 16-bit data word for the TLV5623 consists of two parts:

- Control bits (D15 . . . D12)
- New DAC value (D11 . . . D0)

D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
X	SPD	PWR	X	New DAC value (8 bits)								0	0	0	0

X: don't care

SPD: Speed control bit. 1 → fast mode 0 → slow mode

PWR: Power control bit. 1 → power down 0 → normal operation

In power-down mode, all amplifiers within the TLV5623 are disabled.

APPLICATION INFORMATION

TLV5623 interfaced to TMS320C203 DSP

hardware interfacing

Figure 17 shows an example how to connect the TLV5623 to a TMS320C203 DSP. The serial interface of the TLV5623 is ideally suited to this configuration, using a maximum of four wires to make the necessary connections. In applications where only one synchronous serial peripheral is used, the interface can be simplified even further by pulling $\overline{\text{CS}}$ low all the time as shown in the figure.

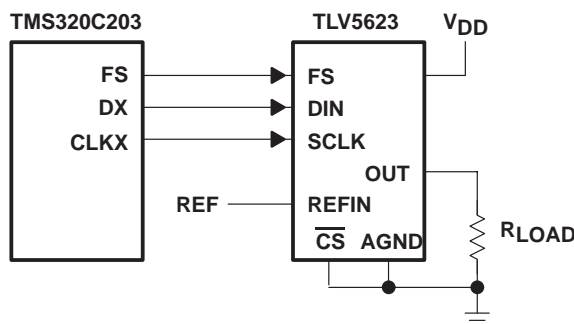

Figure 17. TLV5623 to DSP Interface

TLV5623 interfaced to MCS51[®] microcontroller

hardware interfacing

Figure 18 shows an example of how to connect the TLV5623 to an MCS51[®] compatible microcontroller. The serial DAC input data and external control signals are sent via I/O port 3 of the controller. The serial data is sent on the RxD line, with the serial clock output on the TxD line. P3.4 and P3.5 are configured as outputs to provide the chip select and frame sync signals for the TLV5623.

APPLICATION INFORMATION

linearity, offset, and gain error using single ended supplies

When an amplifier is operated from a single supply, the voltage offset can still be either positive or negative. With a positive offset, the output voltage changes on the first code change. With a negative offset, the output voltage may not change with the first code, depending on the magnitude of the offset voltage.

The output amplifier attempts to drive the output to a negative voltage. However, because the most negative supply rail is ground, the output cannot drive below ground and clamps the output at 0 V.

The output voltage then remains at zero until the input code value produces a sufficient positive output voltage to overcome the negative offset voltage, resulting in the transfer function shown in Figure 19.

Figure 19. Effect of Negative Offset (single supply)

This offset error, not the linearity error, produces this breakpoint. The transfer function would have followed the dotted line if the output buffer could drive below the ground rail.

For a DAC, linearity is measured between zero-input code (all inputs 0) and full-scale code (all inputs 1) after offset and full scale are adjusted out or accounted for in some way. However, single supply operation does not allow for adjustment when the offset is negative due to the breakpoint in the transfer function. So the linearity is measured between full-scale code and the lowest code that produces a positive output voltage.

power-supply bypassing and ground management

Printed-circuit boards that use separate analog and digital ground planes offer the best system performance. Wire-wrap boards do not perform well and should not be used. The two ground planes should be connected together at the low-impedance power-supply source. The best ground connection may be achieved by connecting the DAC AGND terminal to the system analog ground plane, making sure that analog ground currents are well managed and there are negligible voltage drops across the ground plane.

A 0.1- μ F ceramic-capacitor bypass should be connected between V_{DD} and AGND and mounted with short leads as close as possible to the device. Use of ferrite beads may further isolate the system analog supply from the digital power supply.

Figure 20 shows the ground plane layout and bypassing technique.

Figure 20. Power-Supply Bypassing

APPLICATION INFORMATION

definitions of specifications and terminology

integral nonlinearity (INL)

The relative accuracy or integral nonlinearity (INL), sometimes referred to as linearity error, is the maximum deviation of the output from the line between zero and full scale excluding the effects of zero code and full-scale errors.

differential nonlinearity (DNL)

The differential nonlinearity (DNL), sometimes referred to as differential error, is the difference between the measured and ideal 1 LSB amplitude change of any two adjacent codes. Monotonic means the output voltage changes in the same direction (or remains constant) as a change in the digital input code.

zero-scale error (E_{ZS})

Zero-scale error is defined as the deviation of the output from 0 V at a digital input value of 0.

gain error (E_G)

Gain error is the error in slope of the DAC transfer function.

signal-to-noise ratio + distortion (S/N+D)

S/N+D is the ratio of the rms value of the output signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc. The value for S/N+D is expressed in decibels.

spurious free dynamic range (SFDR)

SFDR is the difference between the rms value of the output signal and the rms value of the largest spurious signal within a specified bandwidth. The value for SFDR is expressed in decibels.

total harmonic distortion (THD)

THD is the ratio of the rms sum of the first six harmonic components to the rms value of the fundamental signal and is expressed in decibels.
