TL2575, TL2575HV
1-A SIMPLE STEP-DOWN SWITCHING VOLTAGE REGULATORS
SLVS638−MAY 2006

FEATURES

- **Fixed 3.3-V, 5-V, 12-V, and 15-V Options With ±5% Regulation (Max) Over Line, Load, and Temperature Conditions**
- **Adjustable Option With a Range of 1.23 V to 37 V (57 V for HV Version) and ±4% Regulation (Max) Over Line, Load, and Temperature Conditions**
- **Specified 1-A Output Current**
- **Wide Input Voltage Range…4.75 V to 40 V (60 V for HV Version)**
- **Require Only Four External Components (Fixed Versions) and Use Readily Available Standard Inductors**
- **52-kHz (Typ) Fixed-Frequency Internal Oscillator**
- **TTL Shutdown Capability With 50-μA (Typ) Standby Current**
- **High Efficiency…as High as 88% (Typ)**
- **Thermal Shutdown and Current-Limit Protection With Cycle-by-Cycle Current Limiting**

APPLICATIONS

- **Simple High-Efficiency Step-Down (Buck) Regulators**
- **Pre-Regulators for Linear Regulators**
- **On-Card Switching Regulators**
- **Positive-to-Negative Converters (Buck-Boost)**

DESCRIPTION/ORDERING INFORMATION

The TL2575 and TL2575HV greatly simplify the design of switching power supplies by conveniently providing all the active functions needed for a step-down (buck) switching regulator in an integrated circuit. Accepting a wide input voltage range of up to 60 V (HV version) and available in fixed output voltages of 3.3 V, 5 V, 12 V, 15 V, or an adjustable-output version, the TL2575 and TL2575HV have an integrated switch capable of delivering 1 A of load current, with excellent line and load regulation. The device also offers internal frequency compensation, a fixed-frequency oscillator, cycle-by-cycle current limiting, and thermal shutdown. In addition, a manual shutdown is available via an external ON/OFF pin.

The TL2575 and TL2575HV represent superior alternatives to popular three-terminal linear regulators. Due to their high efficiency, the devices significantly reduce the size of the heatsink and, in many cases, no heatsink is required. Optimized for use with standard series of inductors available from several different manufacturers, the TL2575 and TL2575HV greatly simplify the design of switch-mode power supplies by requiring a minimal addition of only four to six external components for operation.

The TL2575 and TL2575HV are characterized for operation over the virtual junction temperature range of −40°C to 125°C.

Figure 1. Typical Application Circuit (Fixed Version)

Absolute Maximum Ratings[(1)]

over operating free-air temperature range (unless otherwise noted)

			MIN	MAX	UNIT
V_{IN}	Supply voltage	TL2575HV		60	V
		TL2575		42	
	$\overline{ON}$/OFF input voltage range		−0.3	V_{IN}	V
	Output voltage to GND (steady state)			−1	V
T_J	Maximum junction temperature			150	°C
T_{stg}	Storage temperature range		−65	150	°C

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

Package Thermal Data[(1)]

PACKAGE	BOARD	θ_{JC}	θ_{JCP}	θ_{JA}
PDIP (N)	High K, JESD 51-7	57°C/W		67°C/W
TO-263 (KTT)	High K, JESD 51-5		TBD	TBD
TO-220 (KV)			TBD	TBD

(1) Maximum power dissipation is a function of T_J(max), θ_{JA}, and T_A. The maximum allowable power dissipation at any allowable ambient temperature is $P_D = (T_J(max) - T_A)/\theta_{JA}$. Operating at the absolute maximum T_J of 150°C can affect reliability.

Recommended Operating Conditions

			MIN	MAX	UNIT

I_{STBY}	Standby quiescent current		OFF ($\overline{ON}$/OFF = 5 V)	25°C		50	200	μA

(1) In the event of an output short or an overload condition, self-protection features lower the oscillator frequency to ~18 kHz and the minimum duty cycle from 5% to ~2%. The resulting output voltage drops to ~40% of its nominal value, causing the average power dissipated by the IC to lower.
(2) Output is not connected to diode, inductor, or capacitor. Output is sourcing current.
(3) FEEDBACK is disconnected from output and connected to 0 V.
(4) To force the output transistor off, FEEDBACK is disconnected from output and connected to 12 V for the adjustable, 3.3-V, and 5-V versions and to 25 V for the 12-V and 15-V versions.

APPLICATION INFORMATION

Input Capacitor (C_{IN})

For stability concerns, an input bypass capacitor (electrolytic, $C_{IN} \geq 47\ \mu F$) needs to be located as close as possible to the regulator. For operating temperatures below −25°C, C_{IN} may need to be larger in value. In addition, since most electrolytic capacitors have decreasing capacitances and increasing ESR as temperature drops, adding a ceramic or solid tantalum capacitor in parallel increases the stability in cold temperatures.

To extend the capacitor operating lifetime, the capacitor RMS ripple current rating should be:

$I_{C,RMS} > 1.2(t_{on}/T)I_{LOAD}$

where

$t_{on}/T = V_{OUT}/V_{IN}$ {buck regulator} and

$t_{on}/T = |V_{OUT}|/(|V_{OUT}| + V_{IN})$ {buck-boost regulator}

Output Capacitor (C_{OUT})

For both loop stability and filtering of ripple voltage, an output capacitor also is required, again in close proximity to the regulator. For best performance, low-ESR aluminum electrolytics are recommended, although standard aluminum electrolytics may be adequate for some applications. Based on the following equation:

Output ripple voltage = (ESR of C_{OUT}) × (inductor ripple current)

Output ripple of 50 mV to 150 mV typically can be achieved with capacitor values of 220 µF to 680 µF. Larger C_{OUT} can reduce the ripple 20 mV to 50 mV peak to peak. To improve further on output ripple, paralleling of standard electrolytic capacitors may be used. Alternatively, higher-grade capacitors such as high frequency, low inductance, or low ESR can be used.

The following should be taken into account when selecting C_{OUT}:

- At cold temperatures, the ESR of the electrolytic capacitors can rise dramatically (typically 3× nominal value at −25°C). Because solid tantalum capacitors have significantly better ESR specifications at cold temperatures, they should be used at operating temperature lower than −25°C. As an alternative, tantalums also can be paralleled to aluminum electrolytics and should contribute 10% to 20% to the total capacitance.
- Low ESR for C_{OUT} is desirable for low output ripple. However, the ESR should be greater than 0.05 Ω to avoid the possibility of regulator instability. Hence, a sole tantalum capacitor used for C_{OUT} is most susceptible to this occurrence.
- The capacitor's ripple current rating of 52 kHz should be at least 50% higher than the peak-to-peak inductor ripple current.

Catch Diode

As with other external components, the catch diode should be placed close to the output to minimize unwanted noise. Schottky diodes have fast switching speeds and low forward voltage drops and, thus, offer the best performance, especially for switching regulators with low output voltages ($V_{OUT} < 5$ V). If a high-efficiency, fast-recovery, or ultra-fast-recovery diode is used in place of a Schottky, it should have a soft recovery (versus abrupt turn-off characteristics) to avoid the chance of causing instability and EMI. Standard 50-/60-Hz diodes, such as the 1N4001 or 1N5400 series, are not suitable.

APPLICATION INFORMATION (continued)

Inductor

Proper inductor selection is key to the performance-switching power-supply designs. One important factor to consider is whether the regulator is used in continuous mode (inductor current flows continuously and never drops to zero) or in discontinuous mode (inductor current goes to zero during the normal switching cycle). Each mode has distinctively different operating characteristics and, therefore, can affect the regulator performance and requirements. In many applications, the continuous mode is the preferred mode of operation, since it offers greater output power with lower peak currents, and also can result in lower output ripple voltage. The advantages of continuous mode of operation come at the expense of a larger inductor required to keep inductor current continuous, especially at low output currents and/or high input voltages.

The TL2575 and TL2575HV can operate in either continuous or discontinuous mode. With heavy load currents, the inductor current flows continuously and the regulator operates in continuous mode. Under light load, the inductor fully discharges and the regulator is forced into the discontinuous mode of operation. For light loads (approximately 200 mA or less), this discontinuous mode of operation is perfectly acceptable and may be desirable solely to keep the inductor value and size small. Any buck regulator eventually operates in discontinuous mode when the load current is light enough.

The type of inductor chosen can have advantages and disadvantages. If high performance/quality is a concern, then more-expensive toroid core inductors are the best choice, as the magnetic flux is contained completely within the core, resulting in less EMI and noise in nearby sensitive circuits. Inexpensive bobbin core inductors, however, generate more EMI as the open core does not confine the flux within the core. Multiple switching regulators located in proximity to each other are particularly susceptible to mutual coupling of magnetic fluxes from each other's open cores. In these situations, closed magnetic structures (such as a toroid, pot core, or E-core) are more appropriate.

Regardless of the type and value of inductor used, the inductor never should carry more than its rated current. Doing so may cause the inductor to saturate, in which case the inductance quickly drops, and the inductor looks like a low-value resistor (from the dc resistance of the windings). As a result, switching current rises dramatically (until limited by the current-by-current limiting feature of the TL2575 and TL2575HV) and can result in overheating of the inductor and the IC itself. Note that different types of inductors have different saturation characteristics.

Output Voltage Ripple and Transients

As with any switching power supply, the output of the TL2575 and TL2575HV have a sawtooth ripple voltage at the switching frequency. Typically about 1% of the output voltage, this ripple is due mainly to the inductor sawtooth ripple current and the ESR of the output capacitor (see note on C_{OUT}). Furthermore, the output also may contain small voltage spikes at the peaks of the sawtooth waveform. This is due to the fast switching of the output switch and the parasitic inductance of C_{OUT}. These voltage spikes can be minimized through the use of low-inductance capacitors.

There are several ways to reduce the output ripple voltage: a larger inductor, a larger C_{OUT}, or both. Another method is to use a small LC filter (20 µH and 100 µF) at the output. This filter can reduce the output ripple voltage by a factor of 10 (see Figure 2).

Feedback Connection

For fixed-voltage options, FEEDBACK must be wired to V_{OUT}. For the adjustable version, FEEDBACK must be connected between the two programming resistors. Again, both of these resistors should be in close proximity to the regulator, and each should be less than 100 kΩ to minimize noise pickup.

$\overline{ON}$/OFF Input

$\overline{ON}$/OFF should be grounded or be a low-level TTL voltage (typically <1.6 V) for normal operation. To shut down the TL2575 or TL2575HV and put it in standby mode, a high-level TTL or CMOS voltage should be supplied to this pin. $\overline{ON}$/OFF should not be left open and safely can be pulled up to V_{IN} with or without a pullup resistor.

APPLICATION INFORMATION (continued)

Grounding

The power and ground connections of the TL2575 and TL2575HV must be low impedance to help maintain output stability. For the 5-pin packages, both pin 3 and tab are ground, and either connection can be used as they are both part of the same lead frame. With the 16-pin package, all the ground pins (including signal and power grounds) should be soldered directly to wide PCB copper traces to ensure low-inductance connections and good thermal dissipation.

Layout Guidelines

With any switching regulator, circuit layout plays an important role in circuit performance. Wiring and parasitic inductances, as well as stray capacitances, are subjected to rapidly switching currents, which can result in unwanted voltage transients. To minimize inductance and ground loops, the length of the leads indicated by heavy lines should be minimized. Optimal results can be achieved by single-point grounding (see Figure 2) or by ground-plane construction. For the same reasons, the two programming resistors used in the adjustable version should be located as close as possible to the regulator to keep the sensitive feedback wiring short.

BUCK REGULATOR DESIGN PROCEDURE

PROCEDURE (Fixed Output)	EXAMPLE (Fixed Output)
Known: V_{OUT} = 3.3 V, 5 V, 12 V, or 15 V $V_{IN(Max)}$ = Maximum input voltage $I_{LOAD(Max)}$ = Maximum load current	**Known:** V_{OUT} = 5 V $V_{IN(Max)}$ = 20 V $I_{LOAD(Max)}$ = 1 A

1. Inductor Selection (L1)
 	
A. From Figure 15 through Figure 18, select the appropriate inductor code based on the intersection of $V_{IN(Max)}$ and $I_{LOAD(Max)}$.
 	
B. From Table 2, choose the appropriate inductor based on the inductor code. Parts from three well-known inductor manufacturers are given. The inductor chosen should be rated for operation at 52-kHz and have a current rating of at least $1.15 \times I_{LOAD(Max)}$ to allow for the ripple current. The actual peak current in L1 (in normal operation) can be calculated as follows:
$I_{L1(pk)} = I_{LOAD(Max)} + (V_{IN} - V_{OUT}) \times t_{on}/2L1$
Where $t_{on} = V_{OUT}/V_{IN} \times (1/f_{osc})$
	1. Inductor Selection (L1)
	
	A. From Figure 16 (TL2575-05), the intersection of 20-V line and 1-A line gives an inductor code of L330.
	
	B. L330 $\rightarrow$ L1 = 330 μH
	Choose from:
	    34042 (Schott)
	    PE-52627 (Pulse Engineering)
	    RL1952 (Renco)

2. Output Capacitor Selection (C_{OUT}) **A.** The TL2575 control loop has a two-pole two-zero frequency response. The dominant pole-zero pair is established by C_{OUT} and L1. To meet stability requirements while maintaining an acceptable output ripple voltage ($V_{ripple} \approx 0.01 \times V_{OUT}$), the recommended range for a standard aluminum electrolytic C_{OUT} is between 100 μF and 470 μF. **B.** C_{OUT} should have a voltage rating of at least $1.5 \times V_{OUT}$. But if a low output ripple voltage is desired, choose capacitors with a higher-voltage ratings than the minimum required, due to their typically lower ESRs.	**2. Output Capacitor Selection (C_{OUT})** **A.** C_{OUT} = 100-μF to 470-μF, standard aluminum electrolytic **B.** Although a C_{OUT} rated at 8 V is sufficient for V_{OUT} = 5 V, a higher-voltage capacitor is chosen for its typically lower ESR (and hence lower output ripple voltage) $\rightarrow$ Capacitor voltage rating = 20 V.
3. Catch Diode Selection (D1) (see Table 1) **A.** In normal operation, the catch diode requires a current rating of at least $1.2 \times I_{LOAD(Max)}$. For the most robust design, D1 should be rated to handle a current equal to the TL2575 maximum switch peak current; this represents the worst-case scenario of a continuous short at V_{OUT}. **B.** The diode requires a reverse voltage rating of at least $1.25 \times V_{IN(Max)}$.	**3. Catch Diode Selection (D1) (see Table 1)** **A.** Pick a diode with 3-A rating. **B.** Pick 30-V rated Schottky diode (1N5821, MBR330, 31QD03, or SR303) or 100-V rated Fast Recovery diode (31DF1, MURD310, or HER302).
4. Input Capacitor (C_{IN}) An aluminum electrolytic or tantalum capacitor is needed for input bypassing. Locate C_{IN} as close to the V_{IN} and GND pins as possible.	**4. Input Capacitor (C_{IN})** C_{IN} = 100 μF, 25 V, aluminum electrolytic

PROCEDURE (Adjustable Output)	EXAMPLE (Adjustable Output)
Known: $V_{OUT(Nom)}$ $V_{IN(Max)}$ = Maximum input voltage $I_{LOAD(Max)}$ = Maximum load current	**Known:** V_{OUT} = 10 V $V_{IN(Max)}$ = 25 V $I_{LOAD(Max)}$ = 1 A
1. Programming Output Voltage (Selecting R1 and R2) Referring to Fig. 2, V_{OUT} is defined by: $V_{OUT} = V_{REF}\left(1 + \dfrac{R2}{R1}\right)$ where V_{REF} = 1.23 V Choose a value for R1 between 1 kΩ and 5 kΩ (use 1% metal-film resistors for best temperature coefficient and stability over time). $R2 = R1\left(\dfrac{V_{OUT}}{V_{REF}} - 1\right)$	**1. Programming Output Voltage (Selecting R1 and R2)** Select R1 = 1 kΩ R2 = 1 (10/1.23 − 1) = 7.13 kΩ Select R2 = 7.15 kΩ (closest 1% value)

2. Inductor Selection (L1)
 	
A. Calculate the "set" volts-second (E•T) across L1:
$E{\bullet}T = (V_{IN} - V_{OUT}) \times t_{on}$
$E{\bullet}T = (V_{IN} - V_{OUT}) \times (V_{OUT}/V_{IN}) \times \{1000/f_{osc}(\text{in kHz})\}$ [V•μs]
NOTE: Along with I_{LOAD}, the "set" volts-second (E•T) constant establishes the minimum energy storage requirement for the inductor.
 	
B. Using Figure 19, select the appropriate inductor code based on the intersection of E•T value and $I_{LOAD(Max)}$.
 	
C. From Table 2, choose the appropriate inductor based on the inductor code. Parts from three well-known inductor manufacturers are given. The inductor chosen should be rated for operation at 52-kHz and have a current rating of at least 1.15 x $I_{LOAD(Max)}$ to allow for the ripple current. The actual peak current in L1 (in normal operation) can be calculated as follows:
 	
$I_{L1(pk)} = I_{LOAD(Max)} + (V_{IN} - V_{OUT}) \times t_{on}/2L1$
Where $t_{on} = V_{OUT}/V_{IN} \times (1/f_{osc})$
	2. Inductor Selection (L1)
	
	A. Calculate the "set" volts-second (E•T) across L1:
	$E{\bullet}T = (25 - 10) \times (10/25) \times (1000/52)$ [V•μs]
	$E{\bullet}T = 115$ V•μs
	
	B. Using Figure 19, the intersection of 115 V•μs and 1 A corresponds to an inductor code of H470.
	
	C. H470 → L1 = 470 μF
	Choose from:
	    34048 (Schott)
	    PE-53118 (Pulse Engineering)
	    RL1961 (Renco)

3. Output Capacitor Selection (C_{OUT}) **A.** The TL2575 control loop has a two-pole two-zero frequency response. The dominant pole-zero pair is established by C_{OUT} and L1. To meet stability requirements, C_{OUT} must meet the following requirement: $C_{OUT} \geq 7758\,\dfrac{V_{IN(Max)}}{V_{OUT}\,L1(\mu H)}$ (μF) However, C_{OUT} may need to be several times larger than the calculated value above in order to achieve an acceptable output ripple voltage of ~0.01 × V_{OUT}. **B.** C_{OUT} should have a voltage rating of at least 1.5 × V_{OUT}. But if a low output ripple voltage is desired, choose capacitors with a higher voltage ratings than the minimum required due to their typically lower ESRs.	**3. Output Capacitor Selection (C_{OUT})** **A.**$C_{OUT} \geq 7785 \times 25/(10 \times 470)$ [μF] $C_{OUT} \geq 41.4$ μF To obtain an acceptable output voltage ripple → C_{OUT} = 220 μF electrolytic
4. Catch Diode Selection (D1) (see Table 1) **A.** In normal operation, the catch diode requires a current rating of at least 1.2 × $I_{LOAD(Max)}$. For the most robust design, D1 should be rated for a current equal to the TL2575 maximum switch peak current; this represents the worst-case scenario of a continuous short at V_{OUT}. **B.** The diode requires a reverse voltage rating of at least 1.25 × $V_{IN(Max)}$.	**4. Catch Diode Selection (D1) (see Table 1)** **A.** Pick a diode with a 3-A rating. **B.** Pick a 40-V rated Schottky diode (1N5822, MBR340, 31QD04, or SR304) or 100-V rated Fast Recovery diode (31DF1, MURD310, or HER302)
5. Input Capacitor (C_{IN}) An aluminum electrolytic or tantalum capacitor is needed for input bypassing. Locate C_{IN} as close to V_{IN} and GND pins as possible.	**5. Input Capacitor (C_{IN})** C_{IN} = 100 μF, 35 V, aluminum electrolytic

PACKAGING INFORMATION

Orderable Device	Status [1]	Package Type	Package Drawing	Pins	Package Qty	Eco Plan [2]	Lead/Ball Finish	MSL Peak Temp [3]
TL2575-05IN	ACTIVE	PDIP	N	16	25	Pb-Free (RoHS)	CU NIPD	N / A for Pkg Type
TL2575-33IN	ACTIVE	PDIP	N	16	25	Pb-Free (RoHS)	CU NIPD	N / A for Pkg Type

[1] The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.

[2] Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check http://www.ti.com/productcontent for the latest availability information and additional product content details.
TBD: The Pb-Free/Green conversion plan has not been defined.
Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.
Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.
Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

[3] MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.
