LOW-INPUT VOLTAGE-MODE SYNCHRONOUS BUCK CONTROLLER

FEATURES

- Operating Input Voltage 2.25 V to 5.5 V
- Output Voltage as Low as 0.7 V
- 1% Internal 0.7 V Reference
- Predictive Gate Drive™ N-Channel MOSFET Drivers for Higher Efficiency
- Externally Adjustable Soft-Start and Overcurrent Limit
- Source-Only Current or Source/Sink Current
- Versions for Starting Into V_{OUT} Pre-Bias
- 10-Lead MSOP PowerPad™ Package for Higher Performance
- Thermal Shutdown
- Internal Bootstrap Diode
- Fixed-Frequency, Voltage-Mode Control
 - TPS40000/1/4 300-kHz
 - TPS40002/3/5 600-kHz

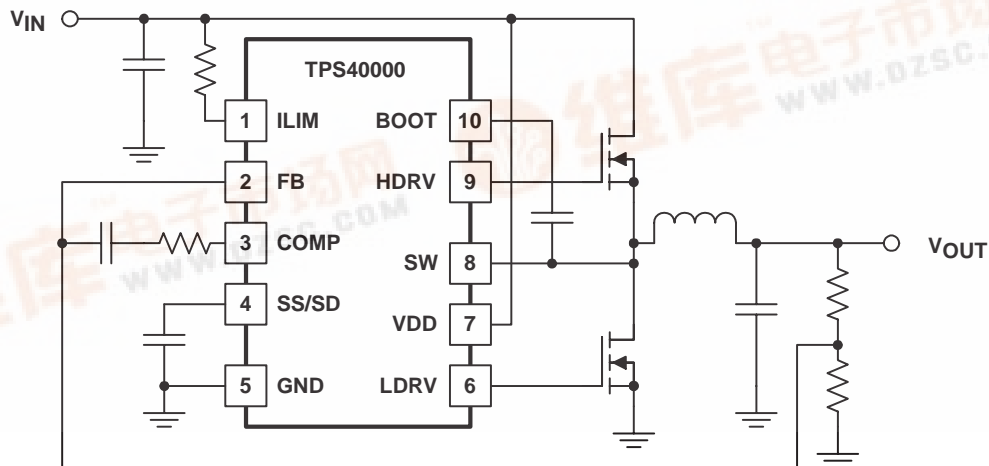

APPLICATIONS

- Networking Equipment
- Telecom Equipment
- Base Stations
- Servers
- DSP Power
- Power Modules

DESCRIPTION

The TPS4000x are controllers for low-voltage, non-isolated synchronous buck regulators. These controllers drive an N-channel MOSFET for the primary buck switch, and an N-channel MOSFET for the synchronous rectifier switch, thereby achieving very high-efficiency power conversion. In addition, the device controls the delays from main switch off to rectifier turn-on and from rectifier turn-off to main switch turn-on in such a way as to minimize diode losses (both conduction and recovery) in the synchronous rectifier with TI's proprietary Predictive Gate Drive™ technology. The reduction in these losses is significant and increases efficiency. For a given converter power level, smaller FETs can be used, or heat sinking can be reduced or even eliminated.

SLUS507C – JANUARY 2002 – REVISED JUNE 2004

DESCRIPTION (continued)

The current-limit threshold is adjustable with a single resistor connected to the device. The TPS4000x controllers implement a closed-loop soft start function. Startup ramp time is set by a single external capacitor connected to the SS/SD pin. The SS/SD pin is also used for shutdown.

ORDERING INFORMATION

T _A	FREQUENCY	PACKAGED DEVICES MSOP ⁽²⁾ (DGQ)		
		APPLICATION		
		SOURCE ONLY	SOURCE/SINK WITH PREBIAS ⁽³⁾	SOURCE/SINK ⁽³⁾
-40°C to 85°C	300 kHz	TPS40000DGQ	TPS40001DGQ	TPS40004DGQ
	600 kHz	TPS40002DGQ	TPS40003DGQ	TPS40005DGQ

(2) The DGQ package is available taped and reeled. Add R suffix to device type (e.g. TPS40000DGQR) to order quantities of 2,500 devices per reel and 80 units per tube.

SLUS507C – JANUARY 2002 – REVISED JUNE 2004

Terminal Functions

TERMINAL		I/O	DESCRIPTION
NAME	NO.		
BOOT	10	O	Provides a bootstrapped supply for the topside MOSFET driver, enabling the gate of the topside MOSFET to be driven above the input supply rail
COMP	3	O	Output of the error amplifier
FB	2	I	Inverting input of the error amplifier. In normal operation the voltage at this pin is the internal reference level of 700 mV.
GND	5	–	Power supply return for the device. The power stage ground return on the board requires a separate path from other sensitive signal ground returns.
HDRVV	9	O	This is the gate drive output for the topside N-channel MOSFET. HDRVV is bootstrapped to near $2 \times V_{DD}$ for good enhancement of the topside MOSFET.
ILIM	1	I	A resistor is connected between this pin and VDD to set up the over current threshold voltage. A 15- μ A current sink at the pin establishes a voltage drop across the external resistor that represents the drain-to-source voltage across the top side N-channel MOSFET during an over current condition. The ILIM over current comparator is blanked for the first 100 ns to allow full enhancement of the top MOSFET. Set the ILIM voltage level such that it is within 800 mV of VDD; that is, $(V_{DD} - 0.8) \leq I_{ILIM} \leq V_{DD}$.
LDRV	6	O	Gate drive output for the low-side synchronous rectifier N-channel MOSFET
SS/SD	4	I	Soft-start and overcurrent fault shutdown times are set by charging and discharging a capacitor connected to this pin. A closed loop soft-start occurs when the internal 3- μ A current source charges the external capacitor from 0.17 V to 0.70 V. During the soft-start period, the current sink capability of the TPS40001 and TPS40003 is disabled. When the SS/SD voltage is less than 0.12 V, the device is shutdown and the HDRVV and LDRV are driven low. In normal operation, the capacitor is charged to 1.5 V. When a fault condition is asserted, the HDRVV is driven low, and the LDRV is driven high. The soft-start capacitor goes through six charge/discharge cycles, restarting the converter on the seventh cycle.
SW	8	O	Connect to the switched node on the converter. This pin is used for overcurrent sensing in the topside N-channel MOSFET, zero current sensing in synchronous rectifier N-channel MOSFET, and level sensing for predictive delay circuit. Overcurrent is determined, when the topside N-channel MOSFET is on, by comparing the voltage on SW with respect to VDD and the voltage on the ILIM with respect to VDD. Zero current is sensed, when the rectifier N-channel MOSFET is on, by measuring the voltage on SW with respect to ground. Zero current sensing applies to the TPS40000/2 devices only.
VDD	7	I	Power input for the chip, 5.5-V maximum. Decouple close to the pin with a low-ESR capacitor, 1- μ F or larger.

SLUS507C – JANUARY 2002 – REVISED JUNE 2004

APPLICATION INFORMATION

The TPS4000x series of synchronous buck controller devices is optimized for high-efficiency dc-to-dc conversion in non-isolated distributed power systems. A typical application circuit is shown in Figure 1.

The TPS40004 and TPS40005 are the controllers of choice for most general purpose synchronous buck designs. Each operates in two quadrant mode (i.e. source or sink current) full time. This choice provides the best performance for output voltage load transient response over the widest load current range.

The TPS40001 and TPS40003 add an additional feature: They operate in single quadrant mode (i.e. source current only) during converter startup, and then when the converter has reached the regulation point, the controllers change to operate in two quadrant mode. This is useful for applications that have outputs pre-biased at some voltage before the controller is enabled. When the TPS40001 or TPS40003 is enabled, it does not sink current during startup and therefore does not pull current from the pre-biased voltage supply.

The TPS40000 and TPS40002 operate in single quadrant mode (source current only) full time, allowing the paralleling of converters. Single quadrant operation ensures one converter does pull current from a paralleled converter. A converter using one of these controllers emulates a non-synchronous buck converter at light loads. When current in the output inductor attempts to reverse, an internal zero-current detection circuit turns OFF the synchronous rectifier and causes the current flow in the inductor to become discontinuous. At average load currents greater than the peak amplitude of the inductor ripple current, the converter returns to operation as a synchronous buck converter to maximize efficiency.

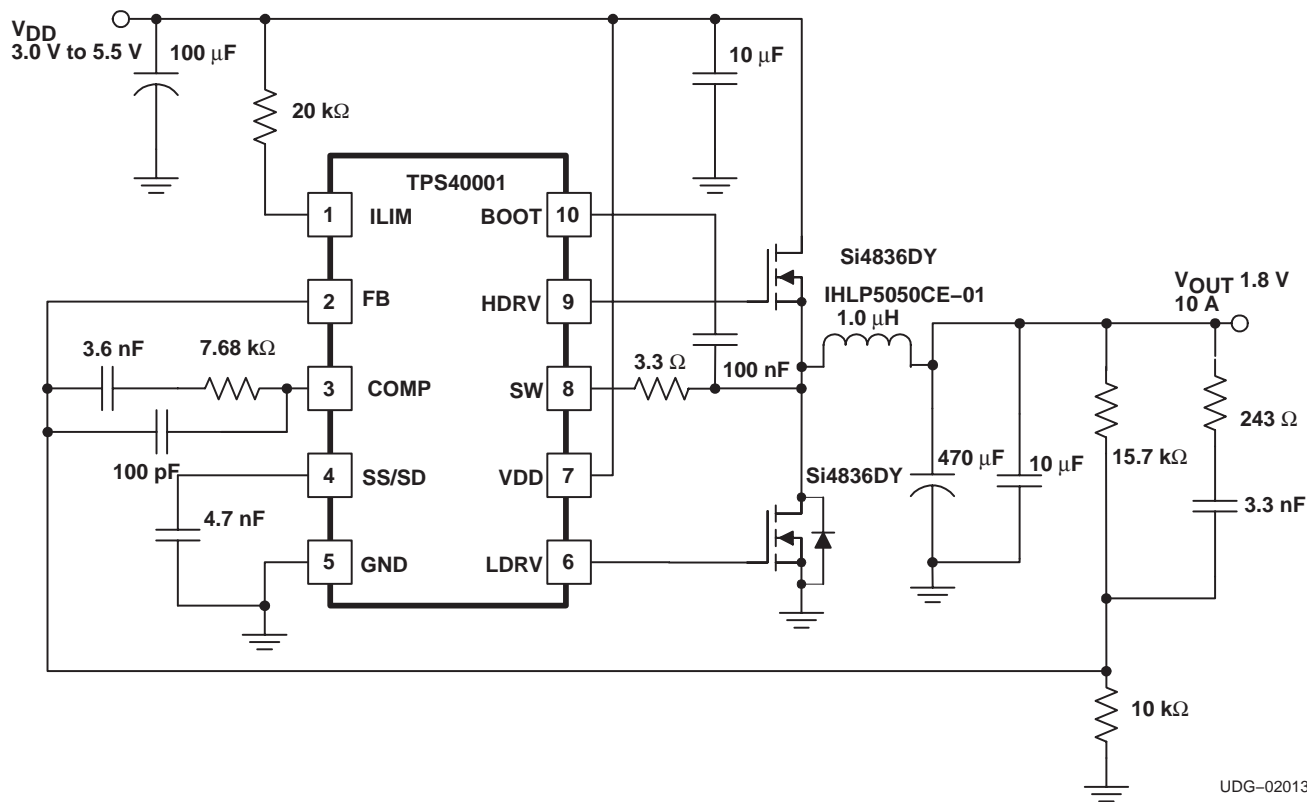

Figure 1. Typical Application Circuit

APPLICATION INFORMATION

error amplifier

The error amplifier has a bandwidth of greater than 5 MHz, with open loop gain of at least 55 dB. The COMP output voltage is clamped to a level above the oscillator ramp in order to improve large-scale transient response.

oscillator

The oscillator uses an internal resistor and capacitor to set the oscillation frequency. The ramp waveform is a triangle at the PWM frequency with a peak voltage of 1.25 V, and a valley of 0.25 V. The PWM duty cycle is limited to a maximum of 95%, allowing the bootstrap capacitor to charge during every cycle.

bootstrap/charge pump

There is an internal switch between VDD and BOOT. This switch charges the external bootstrap capacitor for the floating supply. If the resistance of this switch is too high for the application, an external schottky diode between VDD and BOOT can be used. The peak voltage on the bootstrap capacitor is approximately equal to VDD.

driver

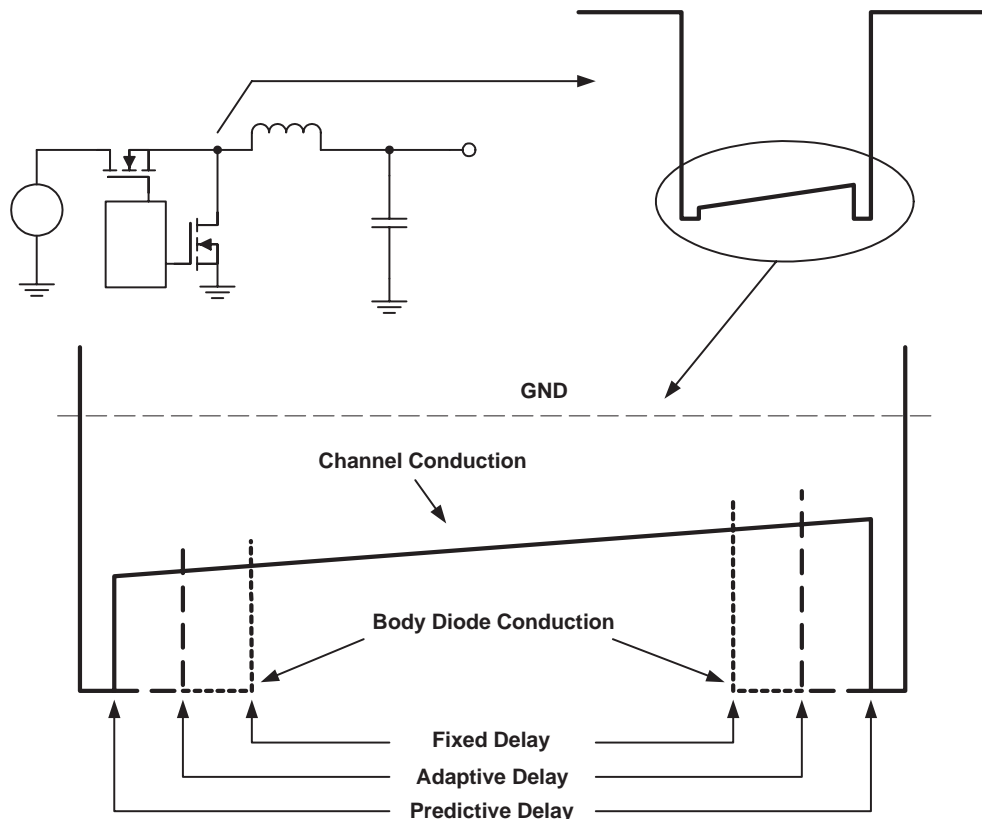

The HDRV and LDRV MOSFET drivers are capable of driving gate-to-source voltages up to 5.5 V. At $V_{IN} = 5$ V and using appropriate MOSFETs, a 20-A converter can be achieved. The LDRV driver switches between VDD and ground, while the HDRV driver is referenced to SW and switches between BOOT and SW. The maximum voltage between BOOT and SW is 5.5 V.

synchronous rectification and predictive delay

In a normal buck converter, when the main switch turns off, current is flowing to the load in the inductor. This current cannot be stopped immediately without using infinite voltage. For the current path to flow and maintain voltage levels at a safe level, a rectifier or catch device is used. This device can be either a conventional diode, or it can be a controlled active device if a control signal is available to drive it. The TPS4000x provides a signal to drive an N-channel MOSFET as a rectifier. This control signal is carefully coordinated with the drive signal for the main switch so that there is minimum delay from the time that the rectifier MOSFET turns off and the main switch turns on, and minimum delay from when the main switch turns off and the rectifier MOSFET turns on. This scheme, Predictive Gate Drive™ delay, uses information from the current switching cycle to adjust the delays that are to be used in the next cycle. Figure 2 shows the switch-node voltage waveform for a synchronously rectified buck converter. Illustrated are the relative effects of a fixed-delay drive scheme (constant, pre-set delays for the turn-off to turn-on intervals), an adaptive delay drive scheme (variable delays based upon voltages sensed on the current switching cycle) and the predictive delay drive scheme.

Note that the longer the time spent in diode conduction during the rectifier conduction period, the lower the efficiency. Also, not described in Figure 2 is the fact that the predictive delay circuit can prevent the body diode from becoming forward biased at all while at the same time avoiding cross conduction or shoot through. This results in a significant power savings when the main MOSFET turns on, and minimizes reverse recovery loss in the body diode of the rectifier MOSFET.

APPLICATION INFORMATION

UDG-01144

Figure 2. Switch Node Waveforms for Synchronous Buck Converter

overcurrent

Overcurrent conditions in the TPS4000x are sensed by detecting the voltage across the main MOSFET while it is on.

basic description

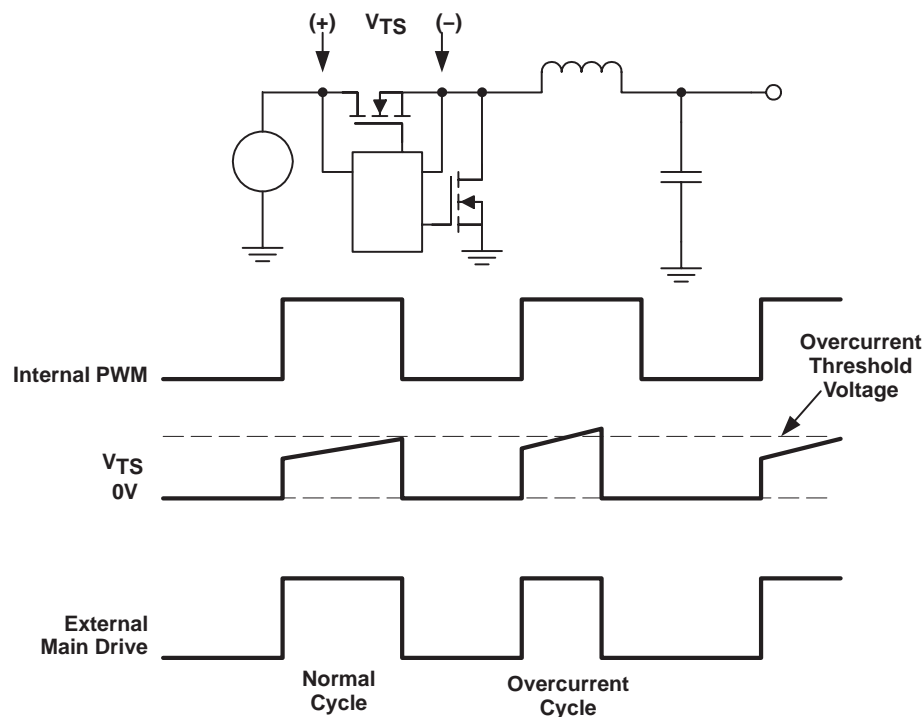

If the voltage exceeds a pre-set threshold, the current pulse is terminated, and a counter inside the device is incremented. If this counter fills up, a fault condition is declared and the device disables switching for a period of time and then attempts to restart the converter with a full soft-start cycle.

APPLICATION INFORMATION

detailed description

During each switching cycle, a comparator looks at the voltage across the top side MOSFET while it is on. This comparator is enabled after the SW node reaches a voltage greater than $(V_{DD}-1.2\text{ V})$ followed by a 100-ns blanking time. If the voltage across that MOSFET exceeds a programmable threshold voltage, the current-switching pulse is terminated and a 3-bit counter is incremented by one count. If, during the switching cycle, the topside MOSFET voltage does not exceed a preset threshold, then this counter is decremented by one count. (The counter does not wrap around from 7 to 0 or from 0 to 7). If the counter reaches a full count of 7, the device declares that a fault condition exists at the output of the converter. In this fault state, HDRV is turned off and LDRV is turned on and the soft-start capacitor is discharged. The counter is decremented by one by the soft start capacitor (C_{SS}) discharge. When the soft-start capacitor is fully discharged, the discharging circuit is turned off and the capacitor is allowed to charge up at the nominal charging rate. When the soft-start capacitor reaches about 700 mV, it is discharged again and the overcurrent counter is decremented by one count. The capacitor is charged and discharged, and the counter decremented until the count reaches zero (a total of six times). When this happens, the outputs are again enabled as the soft-start capacitor generates a reference ramp for the converter to follow while attempting to restart.

During this soft-start interval (whether or not the controller is attempting to do a fault recovery or starting for the first time), pulse-by-pulse current limiting is in effect, but overcurrent pulses are not counted to declare a fault until the soft-start cycle has been completed. It is possible to have a supply attempt to bring up a short circuit for the duration of the soft start period plus seven switching cycles. Power stage designs should take this into account if it makes a difference thermally. Figure 3 shows the details of the overcurrent operation.

UDG-01145

Figure 3. Switch Node Waveforms for Synchronous Buck Converter

APPLICATION INFORMATION

Figure 4 shows the behavior of key signals during initial startup, during a fault and a successfully fault recovery. At time t_0 , power is applied to the converter. The voltage on the soft-start capacitor (V_{CSS}) begins to ramp up and acts as the reference until it passes the internal reference voltage at t_1 . At this point the soft-start period is over and the converter is regulating its output at the desired voltage level. From t_0 to t_1 , pulse-by-pulse current limiting is in effect, and from t_1 onward, overcurrent pulses are counted for purposes of determining a possible fault condition. At t_2 , a heavy overload is applied to the converter. This overload is in excess of the overcurrent threshold. The converter starts limiting current and the output voltage falls to some level depending on the overload applied. During the period from t_2 to t_3 , the counter is counting overcurrent pulses, and at time t_3 reaches a full count of 7. The soft-start capacitor is then discharged, the counter is decremented, and a fault condition is declared.

UDG-01144

Figure 4. Switch Node Waveforms for Synchronous Buck Converter

When the soft start capacitor is fully discharged, it begins charging again at the same rate that it does on startup, with a nominal 3- μ A current source. As the capacitor voltage reaches full charge, it is discharged again and the counter is decremented by one count. These transitions occur at t_3 through t_9 . At t_9 , the counter has been decremented to 0. The fault logic is then cleared, the outputs are enabled, and the converter attempts to restart with a full soft-start cycle. The converter comes into regulation at t_{10} .

APPLICATION INFORMATION

setting the current limit

Connecting a resistor from VDD to ILIM sets the current limit. A 15- μ A current sink internal to the device causes a voltage drop at ILIM that is equal to the overcurrent threshold voltage. Ensure that $(V_{DD}-0.8\text{ V}) \leq V_{ILIM} \leq V_{DD}$. The tolerance of the current sink is too loose to do an accurate current limit. The main purpose is for hard fault protection of the power switches. Given the tolerance of the ILIM sink current, and the $R_{DS(on)}$ range for a MOSFET, it is generally possible to apply a load that thermally damages the converter. This device is intended for embedded converters where load characteristics are defined and can be controlled.

soft-start and shutdown

These two functions are common to the SS/SD pin. The voltage at this pin is the controlling voltage of the error amplifier during startup. This reduces the transient current required to charge the output capacitor at startup, and allows for a smooth startup with no overshoot of the output voltage if done properly. A shutdown feature can be implemented as shown in Figure 5.

UDG-01143

Figure 5. Shutdown Implementation

The device shuts down when the voltage at the SS/SD pin falls below 120 mV. Because of this limitation, it is recommended that a MOSFET be used as the controlling device, as in Figure 5. An open-drain CMOS logic output would work equally well.

rectifier zero-current

Both the TPS40000 and TPS40002 parts are source-only, thus preventing reverse current in the synchronous rectifier. Synchronous rectification is terminated by sensing the voltage, SW with respect to ground, across the low-side MOSFET. When SW node is greater than -7 mV , rectification is terminated and stays off until the next PWM cycle. In order to filter out undesired noise on the SW node, the zero-current comparator is blanked for 75 ns from the time the rectifier is turned on.

The TPS40001 and TPS40003 parts enable the zero-current comparator, (and therefore prevent reverse current), while soft-start is active. However, when the output reaches regulation; that is, at the end of the soft-start time, this comparator is disabled to allow the synchronous rectifier to sink current.
