### ■ General Description

The XC9503 series are PWM controlled, PWM/PFM automatic switching controlled, multi-functional, 2 channel step-down DC/DC controller ICs. Since the series has a built-in 0.9V reference voltage (accuracy  $\pm 2\%$ ), 0.9V to 6.0V can be set using external components. With a 300kHz frequency, the size of the external components can be reduced. Switching frequencies of 180kHz & 500kHz are also available as custom-designed products.

The control of the XC9503 series can be switched between PWM control and PWM/PFM automatic switching control using external signals. Control switches from PWM to PFM during light loads when automatic switching is selected and the series is highly efficient from light loads through to large output currents.

Noise is easily reduced with PWM control since the frequency is fixed. The series gives freedom to select control suited to the application. Soft-start time is internally set to 10msec and offers protection against in-rush currents when the power is switched on and also protects against voltage overshoot.

### ■ Applications

- PDAs
- Palm Top Computers
- Digital Cameras
- Various Multi-Function Power Supplies

### ■ Features

Input Voltage Range	: 2.0V ~ 10V
Power Supply Voltage Range	: 2.0V ~ 10V
Output Voltage Range	: 0.9V ~ 6.0V
	Can be set freely with 0.9V ( $\pm 2.0\%$ ) of reference voltage supply and external components.
Oscillation Frequency	: 300kHz $\pm 15\%$ (180kHz, 500kHz custom)
Output Current	: more than 1000mA (VIN=5.0V, VOUT=3.3V)
Stand-By Function	: 3.0 $\mu$ A (MAX.)
Package	: MSOP-10
Soft-Start Time	: 10 ms (internally set)

### ■ Typical Performance Characteristics

XC9503B093A (300kHz, VOUT1:3.3V)

L1=22 $\mu$ H(CDRH5D28), CL1=47 $\mu$ F(Tantalum)

## ■ Operational Description

The XC9503 series are multi-functional, 2 channel step-down DC/DC converter controller ICs with built-in high speed, low ON resistance drivers.

### <Error Amp 1, 2>

The Error Amplifier is designed to monitor the output voltage and it compares the feedback voltage (FB) with the reference voltage. In response to feedback of a voltage lower than the reference voltage, the output voltage of the error amp. decreases.

### <OSC Generator>

This circuit generates the Switching Frequency which in turn generates the reference clock.

### <Ramp Wave Generator 1, 2>

The Ramp Wave Generator generates a saw-tooth waveform based on outputs from the Phase Shift Generator.

### <PWM Comparator 1, 2>

The PWM Comparator compares outputs from the Error Amp. and saw-tooth waveform. When the voltage from the Error Amp's output is low, the external switch will be set to ON.

### <PWM/PFM Controller 1, 2>

This circuit generates PFM pulses.

Control can be switched between PWM control and PWM/PFM automatic switching control using external signals.

The PWM/PFM automatic switching mode is selected when the voltage of the PWM1 (2) pin is less than 0.2V, and the control switches between PWM and PFM automatically depending on the load. As the PFM circuit generates pulses based on outputs from the PWM comparator, shifting between modes occurs smoothly. PWM control mode is selected when the voltage of the PWM1 (2) pin is more than 0.65V. Noise is easily reduced with PWM control since the switching frequency is fixed.

Control suited to the application can easily be selected which is useful in audio applications, for example, where traditionally, efficiencies have been sacrificed during stand-by as a result of using PWM control (due to the noise problems associated with the PFM mode in stand-by).

### <Vref with Soft Start 1, 2>

The reference voltage, Vref (FB pin voltage)=0.9V, is adjusted and fixed by laser trimming (for output voltage settings, please refer to page 8). To protect against inrush current, when the power is switched on, and also to protect against voltage overshoot, soft-start time is set internally to 10ms. It should be noted, however, that this circuit does not protect the load capacitor (CL) from inrush current. With the Vref voltage limited and depending upon the input to the error amps, the operation maintains a balance between the two inputs of the error amps and controls the EXT pin's ON time so that it doesn't increase more than is necessary.

### <Chip Enable Function>

This function controls the operation and shutdown of the IC. When the voltage of the EN1 or EN2 pins is 0.2V or less, the mode will be chip disable, the channel's operations will stop and the EXT pins will be kept at a highlevel (the external P-type MOSFET will be OFF). When both EN1 and EN2 are in a state of chip disable, current consumption will be no more than 3.0  $\mu$ A.

When the EN1 or EN2 pin's voltage is 0.65V or more, the mode will be chip enable and operations will recommence. With soft-start, 95% of the set output voltage will be reached within 10mS (TYP) from the moment of chip enable.

**<Setting of Output Voltage>**

Output voltage can be set by adding external split resistors. Output voltage is determined by the following equation, based on the values of RFB11(RFB21) and RFB12(RFB22). The sum of RFB11(RFB21) and RFB12(RFB22) should normally be 1 MΩ or

$$V_{OUT}=0.9 \times (RFB11+RFB12) / RFB12$$

The value of CFB1(CFB2), speed-up capacitor for phase compensation, should be  $f_{ZFB} = 1 / (2 \times \pi \times CFB1 \times RFB11)$  which is equal to 12kHz. Adjustments are required from 1kHz to 50kHz depending on the application, value of inductance (L), and value of load capacity (CL).

**[Example of Calculation]**

When  $RFB11=200\text{k}\Omega$  and  $RFB12=75\text{k}\Omega$ ,  $V_{OUT1}=0.9 \times (200\text{k}+75\text{k}) / 75\text{k}=3.3\text{V}$ .

**[Typical Example]**

V <sub>OUT</sub> (V)	RFB11 (kΩ)	RFB12 (kΩ)	CFB1 (pF)	V <sub>OUT</sub> (V)	RFB11 (kΩ)	RFB12 (kΩ)	CFB1 (pF)
1.0	30	270	430	2.5	390	220	33
1.5	220	330	62	2.7	360	180	33
1.8	220	220	62	3.0	560	240	24
2.0	330	270	39	3.3	200	75	62
2.2	390	270	33	5.0	82	18	160

The same method can be adopted for channel two also.

**[External Components]**

Tr : \* MOSFET

XP162A12A6P (TOREX P-Channel Power MOSFET)

Note : VGS Breakdown Voltage of this Tr. is 12V  
so please be careful with the power supply voltage.

CL : 16V, 47μF (Tantalum)

Increase capacity according to the equation below  
when the step-up voltage ratio is large and output  
current is high.

$$C = (CL \text{ standard value}) \times (I_{OUT} (\text{mA}) / 500\text{mA}) \times V_{OUT} / V_{IN}$$

Tr : \* PNP MOSFET

2SA1213 (SANYO)

RB : 500Ω (Adjust in accordance with load & Tr.'s HFE.)

Set according to the equation below.

$$RB \leq (V_{IN}-0.7) \times hFE / IC-REXTBH$$

CB : 2200pF (Ceramic)

Set according to the equation below.

$$CB \leq (2 \pi \times RB \times FOSC \times 0.7)$$

The same components can be adopted for both channel 1 and channel 2.

### ■ Notes on Use

#### 1. Checking for Intermittent Oscillation

The XC9503 series is subject to intermittent oscillation in the proximity of the maximum duty if the step-down ratio is low (e.g., from 4.2 V to 3.3 V) or a heavy load is applied where the duty ratio becomes high. Check waveforms at EXT under your operating conditions. A remedy for this problem is to raise the inductance of coil L or increase the load capacitance CL.

#### 2. PWM/PFM Automatic Switching

If PWM/PFM automatic switching control is selected and the step-down ratio is high (e.g., from 10 V to 1.0 V), the control mode remains in PFM setting over the whole load range, since the duty ratio under continuous-duty condition is smaller than the PFM duty ratio of the XC9503 series. The output voltage's ripple voltage becomes substantially high under heavy load conditions, with the XC9503 series appearing to be producing an abnormal oscillation. If this operation becomes a concern, set pins PWM1 and PWM2 to High to set the control mode to PWM setting. For use under the above-mentioned condition, measured data of PWM/PFM automatic switching control shown on the data sheets are available up to  $I_{OUT} = 100\text{ mA}$ .

#### 3. Ratings

Use the XC9503 series and peripheral components within the limits of their ratings.
