# GENERAL DESCRIPTION

The XRT83VSH316 is a fully integrated 16-channel short-haul line interface unit (LIU) that operates from a 1.8V Inner Core and 3.3V I/O power supplies. Using internal termination, the LIU provides one bill of materials to operate in T1, E1, or J1 mode independently on a per channel basis with minimum external components. The LIU features are programmed through a standard parallel microprocessor interface or SPI (Serial Mode). EXAR's LIU has patented high impedance circuits that allow the transmitter outputs and receiver inputs to be high impedance when experiencing a power failure or when the LIU is powered off. Key design features within the LIU optimize 1:1 or 1+1 redundancy and non-intrusive monitoring applications to ensure reliability without using relays.

The on-chip clock synthesizer generates T1/E1/J1 clock rates from a selectable external clock frequency and has five output clock references that can be used for external timing (8kHz, 1.544Mhz, 2.048Mhz, nxT1/J1, nxE1).

Additional features include System Side LOS, AIS, QRSS/PRBS and Line Side RLOS, AIS, QRSS/PRBS, DMO with 16-bit LCV counters and diagnostic loopback modes for each channel.

## APPLICATIONS

- T1 Digital Cross Connects (DSX-1)
- ISDN Primary Rate Interface
- CSU/DSU E1/T1/J1 Interface
- T1/E1/J1 LAN/WAN Routers
- Public Switching Systems and PBX Interfaces
- T1/E1/J1 Multiplexer and Channel Banks
- Integrated Multi-Service Access Platforms (IMAPs)
- Integrated Access Devices (IADs)
- Inverse Multiplexing for ATM (IMA)
- Wireless Base Stations

## FEATURES

- Fully integrated 16-Channel short haul transceivers for T1/J1 (1.544MHz) and E1 (2.048MHz) applications

- Parallel or SPI Microprocessor Interface

- T1/E1/J1 short haul and clock rate are per port selectable through software without changing components

- Internal Impedance matching on both receive and transmit for 75Ω (E1), 100Ω (T1), 110Ω (J1), and 120Ω (E1) applications are per port selectable through software without changing components

- Power down on a per channel basis with independent receive and transmit selection

- Five pre-programmed transmit pulse settings for T1 short haul applications per channel

- User programable Arbitrary Pulse mode for T1 and E1

- On-Chip transmit short-circuit protection and limiting protects line drivers from damage on a per channel basis

- Crystal-Less digital jitter attenuators (JA) with 32-Bit or 64-Bit FIFO for the receive or transmit path per channel

- Driver failure monitor output (DMO) alerts of possible system or external component problems

- Transmit outputs and receive inputs may be "High" impedance for protection or redundancy applications on a per channel basis

- Support for automatic protection switching

- 1:1 and 1+1 protection without relays

- Receive monitor mode handles 0 to 6dB resistive attenuation (flat loss) along with 0 to 6dB cable loss for both T1 and E1

- Loss of signal (LOS) according to ITU-T G.775/ETS300233 (E1) and ANSI T1.403 (T1/J1) for system (SLOS) and line (RLOS) side diagnostics

- Programmable data stream muting upon RLOS detection

- On-Chip HDB3/B8ZS encoder/decoder with an internal 16-bit LCV counter for each channel

- On-Chip digital clock recovery circuit for high input jitter tolerance

- QRSS/PRBS pattern generator and detection for testing and monitoring for system (SPRBS) and line (PRBS) side diagnostics

- Error and bipolar violation insertion and detection

- Transmit all ones (TAOS) Generators and Detectors for system (SAIS) and line (AIS) side diagnostics

- Supports local analog, remote, digital, and dual loopback modes

- Supports gapped clocks for mapper/multiplexer applications

- 1.8V Digital Core

- 3.3V I/O and Analog Core

- 316-Pin STBGA package

- -40°C to +85°C Temperature Range

## PRODUCT ORDERING INFORMATION

| $\overline{\text{Reset}}$ | D16 | I | **Hardware Reset Input**<br>Active low signal.  When this pin is pulled "Low" for more than 10µS, the internal registers are set to their default state.  See the register description for the default values.<br>*NOTE:  Internally pulled "High" with a 50KΩ resistor.* |
| $\overline{\text{CS5}}$<br>$\overline{\text{CS4}}$<br>$\overline{\text{CS3}}$<br>$\overline{\text{CS2}}$<br>$\overline{\text{CS1}}$ | C16<br>C17<br>B17<br>B18<br>A18 | O | **Chip Select Output**<br>The XRT83VSH316 can be used to provide the necessary chip selects for up to 5 additional devices by using the CSdec[2:0] input pins.  The LIU allows up to 84-channel applications with only using one chip select.  See the CSdec[2:0] definition in the pin description. |
| GPIO1<br>GPIO0 | T16<br>R16 | I/O | **General Purpose Input/Output**<br>These two GPIO pins are controlled through the internal registers in the microprocessor block. One register controls the direction, while the other register is used to store or retrieve the status of these pins. |

### RECEIVER SECTION

| NAME | PIN | TYPE | DESCRIPTION |
|------|-----|------|-------------|
| RxON | Y16 | I | **Receive On/Off Input**<br><br>Upon power up, the receivers are powered off. Turning the receivers On or Off can be selected through the microprocessor interface by programming the appropriate channel register if the hardware pin is pulled "High". If the hardware pin is pulled "Low", all channels are automatically turned off.<br><br>***NOTE:*** *Internally pulled "Low" with a 50K$\Omega$ resistor.* |
| RxTSEL | A16 | I | **Receive Termination Control**<br><br>Upon power up, the receivers are in "High" impedance. Switching to internal termination can be selected through the microprocessor interface by programming the appropriate channel register. However, to switch control to the hardware pin, RxTCNTL must be programmed to "1" in the appropriate global register. Once control has been granted to the hardware pin, it must be pulled "High" to switch to internal termination.<br><br>***NOTE:*** *Internally pulled "Low" with a 50k$\Omega$ resistor.*<br><br><table><tr><th>RxTSEL (pin)</th><th>Rx Termination</th></tr><tr><td>0</td><td>External</td></tr><tr><td>1</td><td>Internal</td></tr><tr><td colspan="2">Note: RxTCNTL (bit) must be set to "1"</td></tr></table> |
| RLOS | T4 | O | **Receive Loss of Signal (Global Pin for All 16-Channels)**<br><br>When a line side receive loss of signal occurs for any one of the 16-channels according to ITU-T G.775, the RLOS pin will go "High" for a minimum of one RCLK cycle. RLOS will remain "High" until the loss of signal condition clears. See the Receive Loss of Signal section of this datasheet for more details.<br><br>***NOTE:*** *This pin is for redundancy applications to initiate an automatic switch to the backup card. For individual channel RLOS, see the register map.* |
| SRLOS | T5 | O | **System Receive Loss of Signal (Global Pin for All 16-Channels)**<br><br>When a system side receive loss of signal occurs for any one of the 16-channels according to ITU-T G.775, the SRLOS pin will go "High" for a minimum of one TCLK cycle. SRLOS will remain "High" until the loss of signal condition clears. See the Receive Loss of Signal section of this datasheet for more details. |

*RECEIVER SECTION*

| NAME | PIN | TYPE | DESCRIPTION |
|---|---|---|---|
| RCLK15 | V12 | O | **Receive Clock Output** |
| RCLK14 | R17 | | RCLK is the recovered clock from the incoming data stream.  If the incoming signal is absent or RxON is pulled "Low", RCLK maintains its timing by using an internal master clock as its reference.  Software control (RCLKE) allows RPOS/RNEG data to be updated on either edge of RCLK. |
| RCLK13 | N18 | | |
| RCLK12 | V15 | | |
| RCLK11 | C15 | | |
| RCLK10 | H18 | | *NOTE:  RCLKE is a global setting that applies to all 16 channels.* |
| RCLK9 | F17 | | |
| RCLK8 | C12 | | |
| RCLK7 | C9 | | |
| RCLK6 | F4 | | |
| RCLK5 | H3 | | |
| RCLK4 | C6 | | |
| RCLK3 | V6 | | |
| RCLK2 | N3 | | |
| RCLK1 | R4 | | |
| RCLK0 | V9 | | |

*RECEIVER SECTION*

| NAME | PIN | TYPE | DESCRIPTION |
|------|-----|------|-------------|
| RCLK_IO | C5 | I/O | **Recovered Clock Input/Output:**<br>This bi-directional clock can be used in two different modes:<br>1. As an input, the LIU will use this clock as its internal clock timing synchronization of the 19.44Mhz clock reference.<br>2. As an output, it is one of 16 recoverd line clocks selected by the Recoved Clock Select [4:0] bits and output through this pin.<br>See table below. |

| Recovered Clock Select [4:0] | Selected RCLK |
|------------------------------|---------------|
| 0XXXX | Input |
| 10000 | RCLK0 |
| 10001 | RCLK1 |
| 10010 | RCLK2 |
| 10011 | RCLK3 |
| 10100 | RCLK4 |
| 10101 | RCLK5 |
| 10110 | RCLK6 |
| 10111 | RCLK7 |
| 11000 | RCLK8 |
| 11001 | RCLK9 |
| 11010 | RCLK10 |
| 11011 | RCLK11 |
| 11100 | RCLK12 |
| 11101 | RCLK13 |
| 11110 | RCLK14 |
| 11111 | RCLK15 |

| NAME | PIN | TYPE | DESCRIPTION |
|------|-----|------|-------------|
| RCLK_T1_E1B | V18 | I/O | **Recovered Clock Frequency Select**<br>This bi-directional clock can be used in two different modes along with the RCLK_IO pin.<br>1. As an input (RCLK_IO must be an input), it selects the frequency of the RCLK_IO input. "Low" = E1, "High" = T1.<br>2. As an output (RCLK_IO must be an output), it indicates the frequency of RCLK_IO, "Low" = E1, "High" = T1.<br>*NOTE:  The RCLKSEL[4:0] bits determine whether this pin is an input or output.* |

*RECEIVER SECTION*

| TEST | V3 | I | **Factory Test Mode** <br> For normal operation, the TEST pin should be tied to ground. <br> *NOTE:  Internally pulled "Low" with a 50kΩ resistor.* |
| $\overline{ICT}$ | C3 | I | **In Circuit Testing** <br> When this pin is tied "Low", all output pins are forced to "High" impedance for in circuit testing. <br> *NOTE:  Internally pulled "High" with a 50KΩ resistor.* |
| CMPOUT | L1 | O | **Test Pin** <br> For testing purposes only. For normal operation leave this pin unconnected. |

*CLOCK SECTION*

| NAME | PIN | TYPE | DESCRIPTION |
|---|---|---|---|
| MCLKin | A5 | I | **Master Clock Input**<br>The master clock input can accept a wide range of inputs that can be used to generate T1 or E1 clock rates on a per channel basis. See the register map for details.<br>*NOTE: Internally pulled "Low" with a 50k$\Omega$ resistor.* |
| 8kHzOUT | B3 | O | **8kHz Output Clock** |
| MCLKE1out | A2 | O | **2.048MHz Output Clock** |
| MCLKE1Nout | A3 | O | **2.048MHz, 4.096MHz, 8.192MHz, or 16.384MHz Output Clock**<br>See the register map for programming details. |
| MCLKT1out | B4 | O | **1.544MHz Output Clock** |
| MCLKT1Nout | C4 | O | **1.544MHz, 3.088MHz, 6.176MHz, or 12.352MHz Output Clock**<br>See the register map for programming details. |
| CLK19MHz | M1 | I | **Factory Test Pin**<br>For normal operation, this pin should be left floating. |
| XTAL1 | J1 | I | **Factory Test Pin**<br>For normal operation, this pin should be left floating. |
| XTAL2 | K1 | O | **Factory Test Pin**<br>For normal operation, this pin should be left floating. |

### SPI (SERIAL PERIPHERAL INTERFACE)

*NOTE:* *These pins are only used if the SPI interface is used in place of the parallel microprocessor interface. The SPI Microprocessor interface uses shared pins except for SER/$\overline{PAR}$.*

| NAME | PIN | TYPE | DESCRIPTION |
|---|---|---|---|
| SER/$\overline{PAR}$ | T17 | I | **Serial/Parallel Select Input**<br>This pin is used to select between the parallel microprocessor or serial interface. By default, the parallel microprocessor mode is selected. To configure the device for a serial interface, this pin must be pulled "HIgh".<br>*NOTE:* *Internally pulled "Low" with a 50kΩ resistor.* |
| SCLK/PCLK | U6 | I | **Serial Clock Input**<br>If Pin SER_$\overline{PAR}$ is pulled "High", this input pin is used as the timing reference for the serial microprocessor interface. See the Microprocessor Section of this datasheet for details. |

## 2.0   CLOCK SYNTHESIZER

In system design, fewer clocks on the network card could reduce noise and interference. Network cards that support both T1 and E1 modes must be able to produce 1.544MHz and 2.048MHz transmission data.  The XRT83VSH316 has a built in clock synthesizer that requires only one input clock reference by programming CLKSEL[3:0] in the appropriate global register.  A list of the input clock options is shown in Table 1.

**TABLE 1: INPUT CLOCK SOURCE SELECT**

| CLKSEL[3:0] | INPUT CLOCK REFERENCE |
|---|---|
| 0h (0000) | 2.048 MHz |
| 1h (0001) | 1.544MHz |
| 8h (1000) | 4.096 MHz |
| 9h (1001) | 3.088 MHz |
| Ah (1010) | 8.192 MHz |
| Bh (1011) | 6.176 MHz |
| Ch (1100) | 16.384 MHz |
| Dh (1101) | 12.352 MHz |
| Eh (1110) | 2.048 MHz |
| Fh (1111) | 1.544 MHz |

The single input clock reference is used to generate multiple timing references.  The first objective of the clock synthesizer is to generate 1.544MHz and 2.048MHz for each of the 16 channels.  This allows each channel to operate in either T1 or E1 mode independent from the other channels.  The state of the equalizer control bits in the appropriate channel registers determine whether the LIU operates in T1 or E1 mode.  The second objective is to generate additional output clock references for system use.  The available output clock references are shown in Figure 2.

**FIGURE 2.   SIMPLIFIED BLOCK DIAGRAM OF THE CLOCK SYNTHESIZER**
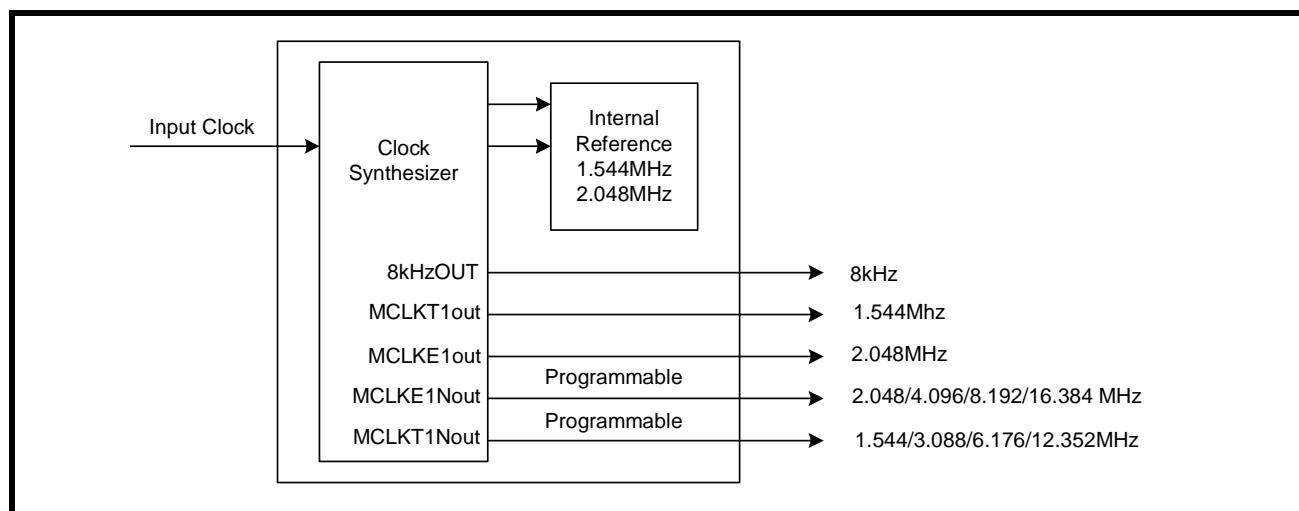

## 3.0 RECEIVE PATH LINE INTERFACE

The receive path of the XRT83VSH316 LIU consists of 16 independent T1/E1/J1 receivers. The following section describes the complete receive path from RTIP/RRING inputs to RCLK/RPOS/RNEG outputs. If any of the diagnostic detection features are used, the LIU must be set in Single Rail mode. Since, the receive path has system diagnostic generators, the part will automatically be placed in Singe Rail Mode whenever one of the diagnostic patterns is used. A simplified block diagram of the receive and transmit path is shown in Figure 3.

**FIGURE 3. SIMPLIFIED BLOCK DIAGRAM OF THE RECEIVE PATH**

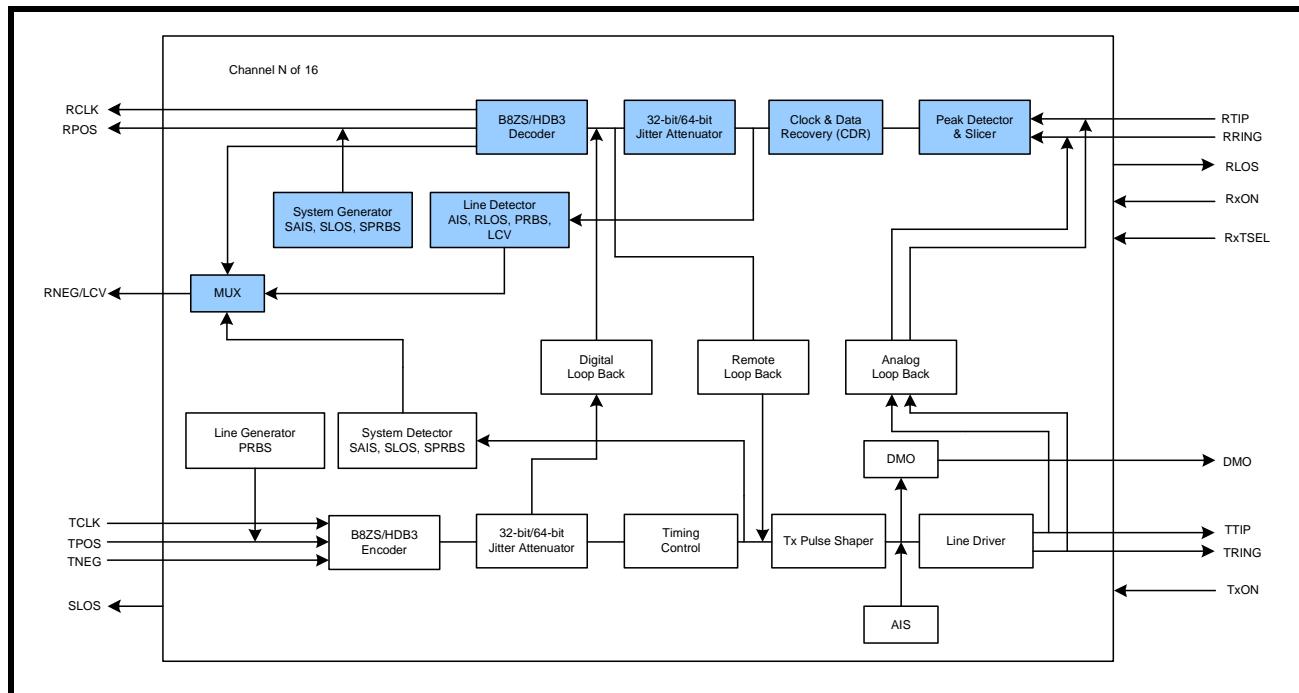

### 3.1 Line Termination (RTIP/RRING)

### 3.1.1 Internal Termination

The input stage of the receive path accepts standard T1/E1/J1 twisted pair or E1 coaxial cable inputs through RTIP and RRING. The physical interface is optimized by placing the terminating impedance inside the LIU. This allows one bill of materials for all modes of operation reducing the number of external components necessary in system design. The receive termination impedance (along with the transmit impedance) is selected by programming TERSEL[1:0] to match the line impedance. Selecting the internal impedance is shown in Table 2.

**TABLE 2: SELECTING THE INTERNAL IMPEDANCE**

| TERSEL[1:0] | TRANSMISSION TERMINATION |
|:---:|:---:|
| 0h (00) | 100Ω |
| 1h (01) | 110Ω |
| 2h (10) | 75Ω |
| 3h (11) | 120Ω |

The XRT83VSH316 has the ability to switch the internal termination to "High" impedance by programming RxTSEL in the appropriate channel register. For internal termination, set RxTSEL to "1". By default, RxTSEL is set to "0" ("High" impedance). For redundancy applications, a dedicated hardware pin (RxTSEL) is also available to control the receive termination for all channels simultaneously. This hardware pin takes priority over the register setting if RxTCNTL is set to "1" in the appropriate global register. If RxTCNTL is set to "0", the state of this pin is ignored. See Figure 4 for a typical connection diagram using the internal termination.

**FIGURE 4.  TYPICAL CONNECTION DIAGRAM USING INTERNAL TERMINATION**

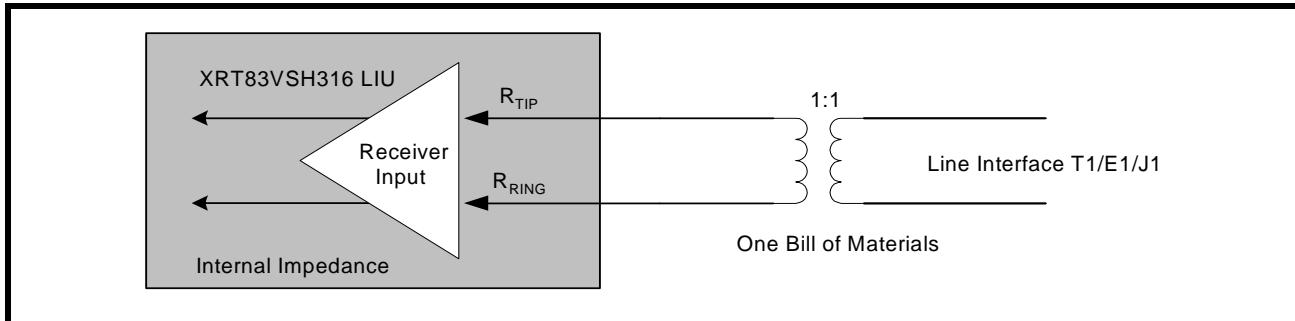

**TABLE 3: RECEIVE TERMINATIONS**

| RXTSEL | TERSEL1 | TERSEL0 | RXRES1 | RXRES0 | $R_{ext}$ | $R_{int}$ | MODE |
|--------|---------|---------|--------|--------|-----------|-----------|------|
| 0 | x | x | x | x | $R_{ext}$ | $\infty$ | **T1/E1/J1** |

| 1 | 1 | 1 | 1 | 1 | 150Ω | 600Ω | E1 |

### 3.2    Clock and Data Recovery

The receive clock (RCLK) is recovered by the clock and data recovery circuitry.  An internal PLL locks on the incoming data stream and outputs a clock that's in phase with the incoming signal.  This allows for multi-channel T1/E1/J1 signals to arrive from different timing sources and remain independent.  In the absence of an incoming signal, RCLK maintains its timing by using the internal master clock as its reference.  The recovered data can be updated on either edge of RCLK.  By default, data is updated on the rising edge of RCLK.  To update data on the falling edge of RCLK, set RCLKE to "1" in the appropriate global register.  Figure 5 is a timing diagram of the receive data updated on the rising edge of RCLK.  Figure 6 is a timing diagram of the receive data updated on the falling edge of RCLK.  The timing specifications are shown in Table 4.

**FIGURE 5.  RECEIVE DATA UPDATED ON THE RISING EDGE OF RCLK**

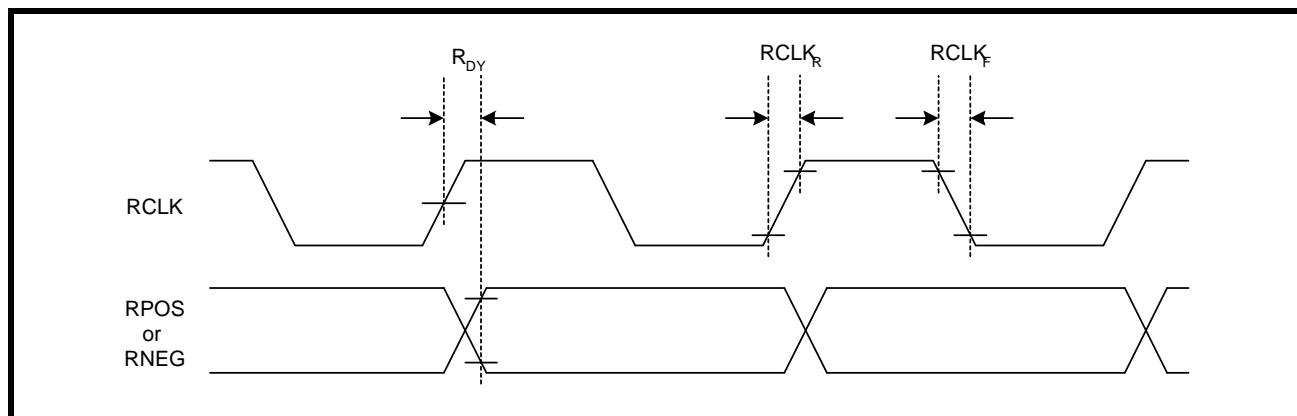

**FIGURE 6.  RECEIVE DATA UPDATED ON THE FALLING EDGE OF RCLK**

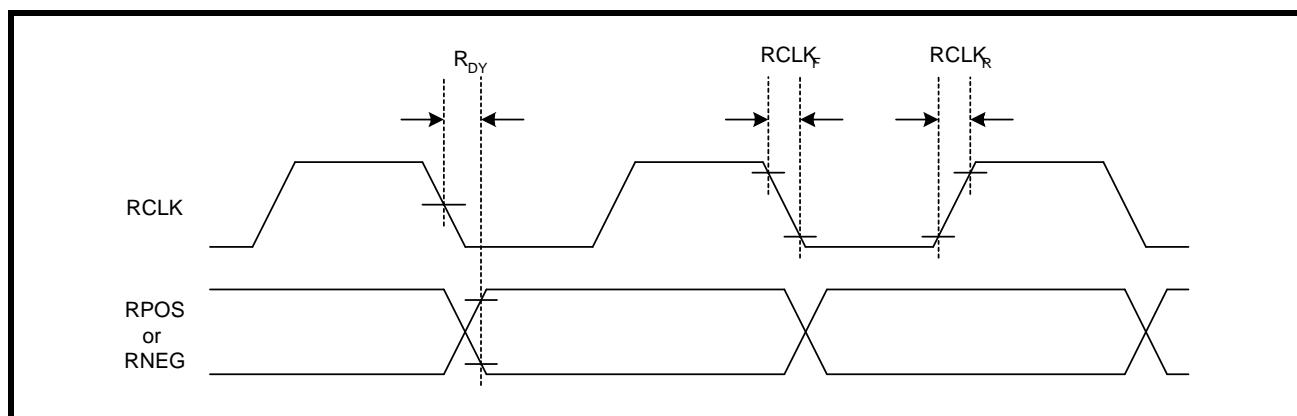

**TABLE 4: TIMING SPECIFICATIONS FOR RCLK/RPOS/RNEG**

| PARAMETER | SYMBOL | MIN | TYP | MAX | UNITS |
|---|---|---|---|---|---|
| RCLK Duty Cycle | $R_{CDU}$ | 45 | 50 | 55 | % |
| RCLK to Data Delay | $R_{DY}$ | - | - | 40 | ns |
| RCLK Rise Time (10% to 90%) with 25pF Loading | $RCLK_R$ | - | - | 40 | ns |
| RCLK Fall Time (90% to 10%) with 25pF Loading | $RCLK_F$ | - | - | 40 | ns |

**NOTE:**  *VDD=3.3V ±5%, VDDc=1.8V ±5%, $T_A$=25°C, Unless Otherwise Specified*

### 3.3 Receive Sensitivity

To meet short haul requirements, the XRT83VSH316 can accept T1/E1/J1 signals that have been attenuated by 12dB of flat loss in E1 or 655ft of cable loss plus 6db of flat loss in T1/J1 mode. Although data integrity is maintained, the RLOS function (if enabled) will report an RLOS condition according to the receiver loss of signal section in this datasheet.  The test configuration for measuring the receive sensitivity is shown in Figure 7.

**FIGURE 7.  TEST CONFIGURATION FOR MEASURING RECEIVE SENSITIVITY**

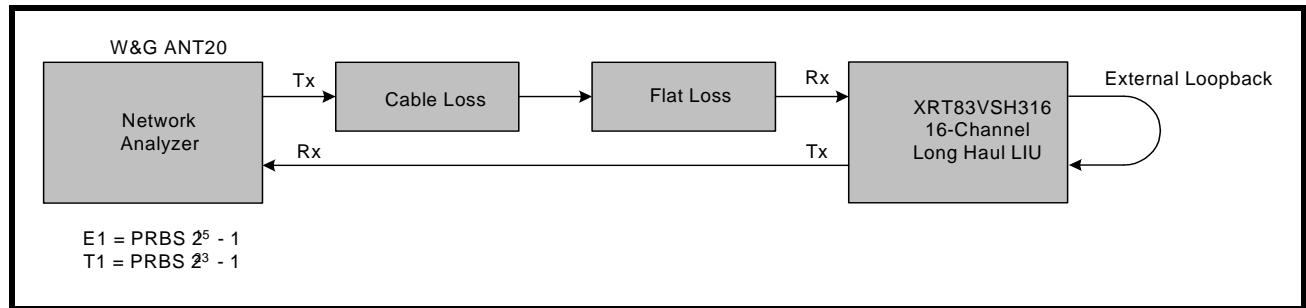

### 3.4 Interference Margin

The test configuration for measuring the interference margin is shown in Figure 8.

**FIGURE 8.  TEST CONFIGURATION FOR MEASURING INTERFERENCE MARGIN**
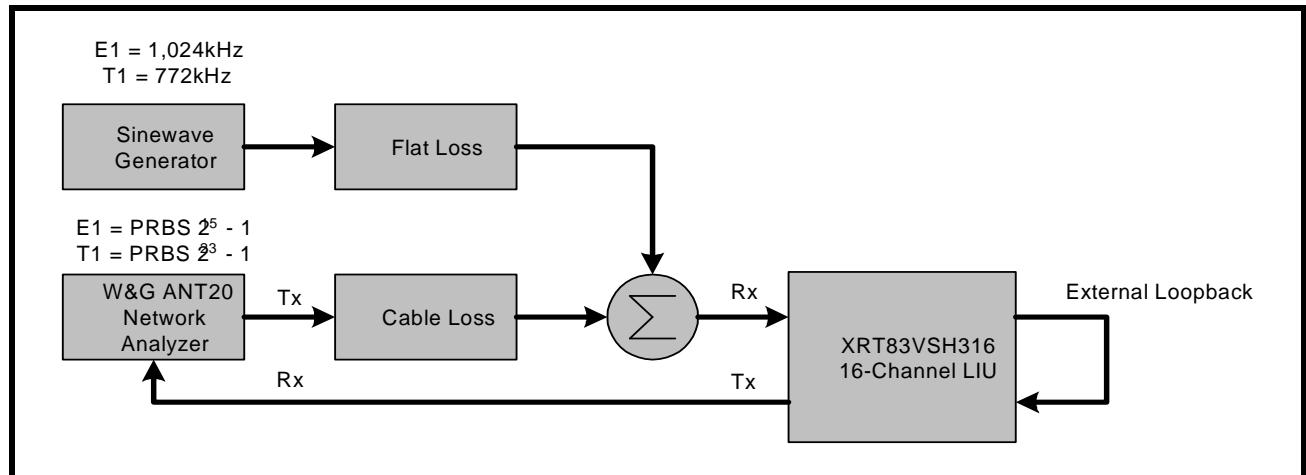

### 3.5    General Alarm Detection and Interrupt Generation

The receive path and transmit path detect RLOS/SLOS, AIS/SAIS, PRBS/SPRBS, and Line Side LCV and DMO. These alarms can be individually masked to prevent the alarm from triggering an interrupt.  To enable interrupt generation, the Global Interrupt Enable (GIE) bit must be set "High" in the appropriate global register. Any time a change in status occurs (it the alarms are enabled), the interrupt pin will pull "Low" to indicate an alarm has occurred.  Once the status registers have been read, the INT pin will return "High".  The status registers are Reset Upon Read (RUR).   The interrupts are categorized in a hierarchical process block. Figure 9 is a simplified block diagram of the interrupt generation process.

**FIGURE 9.  INTERRUPT GENERATION PROCESS BLOCK**

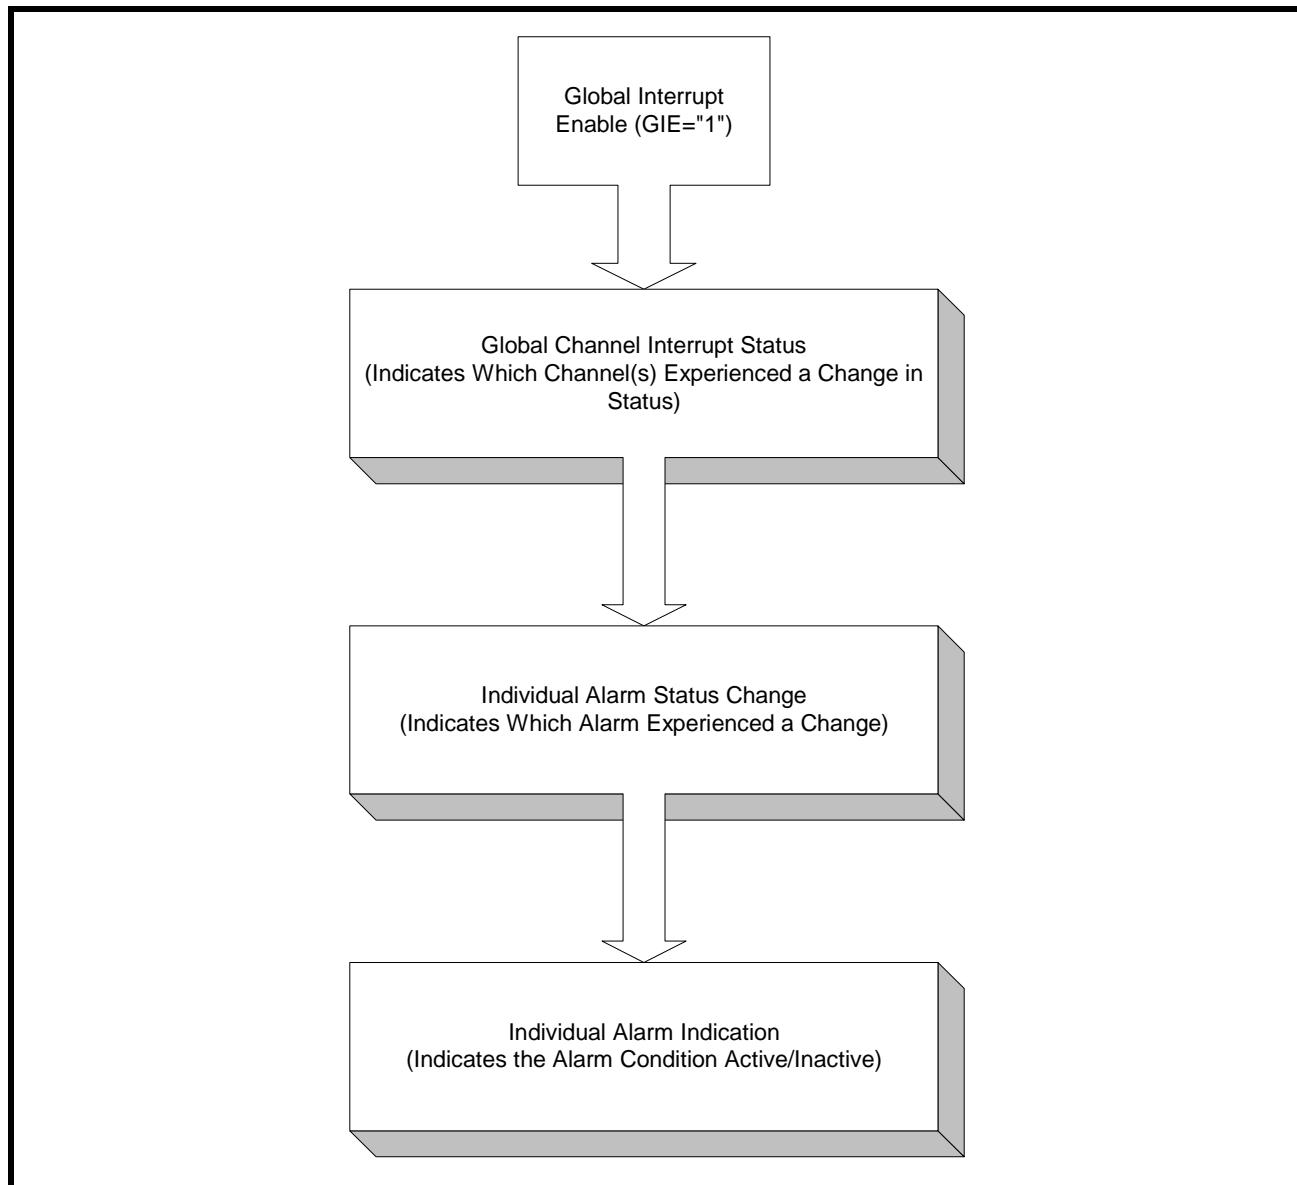

**NOTE:**  *The interrupt pin is an open-drain output that requires a 10kΩ external pull-up resistor.*

### 3.6    Receive Diagnostic Pattern Detection

The receive path has the ability to detect diagnostic patterns on the line side interface from the RTip/RRing input pins (Single Rail Mode Only). The LIU can detect an All Ones (SAIS), Loss of Signal (RLOS), PRBS/ QRSS (SPRBS), or Line Code Violations (LCV).

### 3.6.1    RLOS (Receiver Loss of Signal, Line Side)

The XRT83VSH316 supports both G.775 or ETSI-300-233 RLOS detection scheme.

In G.775 mode, LOS is declared when the received signal is less than 375mV for 32 consecutive pulse periods (typical). The device clears LOS when the receive signal achieves 12.5% ones density with no more than 15 consecutive zeros in a 32 bit sliding window and the signal level exceeds 425mV (typical).

In ETSI-300-233 mode the device declares LOS when the input level drops below 375mV (typical) for more than 2048 pulse periods (1msec).

The device exits LOS when the input signal exceeds 425mV (typical) and has transitions for more than 32 pulse periods with 12.5% ones density with no more than 15 consecutive zero's in a 32 bit sliding window.

In T1 mode RLOS is declared when the received signal is less than 320mV for 175 consecutive pulse period (typical). The device clears RLOS when the receive signal achieves 12.5% ones density with no more than 100 consecutive zeros in a 128 bit sliding window and the signal level exceeds 425mV (typical).

### 3.6.2    EXLOS (Extended Loss of Signal)

By enabling the extended loss of signal by programming the appropriate channel register, the digital LOS is extended to count 4,096 consecutive zeros before declaring LOS in T1 and E1 mode.  By default, EXLOS is disabled and LOS operates in normal mode.

### 3.6.3    AIS (Alarm Indication Signal, Line Side)

The XRT83VSH316 adheres to the ITU-T G.775 specification for an all ones pattern.  The alarm indication signal is set to "1" if an all ones pattern (at least 99.9% ones density) is present for T, where T is 3ms to 75ms in T1 mode.  AIS will clear when the ones density is not met within the same time period T.  In E1 mode, the AIS is set to "1" if the incoming signal has 2 or less zeros in a 512-bit window. AIS will clear when the incoming signal has 3 or more zeros in the 512-bit window.

### 3.6.4    FLSD (FIFO Limit Status Detection)

The purpose of the FIFO limit status is to indicate when the Read and Write FIFO pointers are within a pre-determined range (over-flow or under-flow indication).  The FLSD is set to "1" if the FIFO Read and Write Pointers are within ±3-Bits.

### 3.6.5    LCV (Line Code Violation Detection, Line Side Only)

The LIU contains 16 independent, 16-bit LCV counters.  When the counters reach full-scale, they remain saturated at 0xFFFFh until they are reset globally or on a per channel basis.  For performance monitoring, the counters can be updated globally or on a per channel basis to place the contents of the counters into holding registers.  The LIU uses an indirect address bus to access a counter for a given channel.  Once the contents of the counters have been placed in holding registers, they can be individually read.

The LCV_OF bit supports monitoring of Line Code violations or Over Flow status of the LCV counters. By default, the LCV_OF bit monitors the Line Code Violations and will be set to a "1" if the receiver is currently detecting line code violations or excessive zeros for HDB3 (E1 mode) or B8ZS (T1 mode).  In AMI mode, the LCV_OF will be set to a "1" if the receiver is currently detecting bipolar violations or excessive zeros. However, if the LIU is configured to monitor the 16-bit LCV counter, the LCV_OF will be set to a "1" if the counter saturates.

### 3.7    Receive Diagnostic Pattern Generation

The receive path has the ability to generate diagnostic patterns to the system side interface on the RPOS output pin (Single Rail Mode Only). The LIU can generate an All Ones (SAIS), All Zeros (SLOS), or PRBS/QRSS (SPRBS) signal.

#### 3.7.1    System Side AIS (SAIS)

The system side SAIS signal is an all ones pattern sent to the RPOS output pin. This diagnostic pattern is created by pulling RPOS "High" for the duration it's enabled.

**FIGURE 10.  SYSTEM SIDE SAIS RECEIVE OUTPUT**

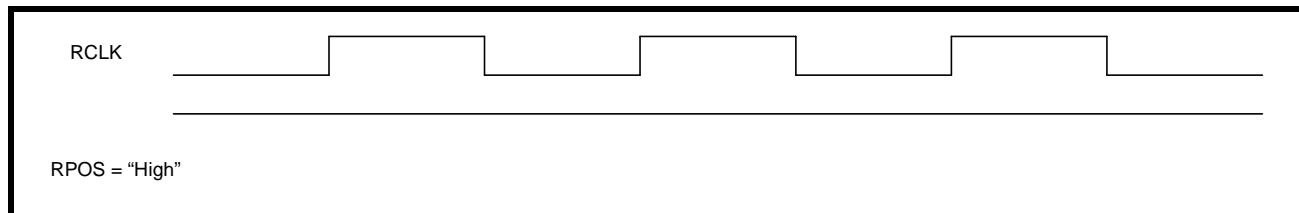

#### 3.7.2    ATAOS (System Automatic Transmit All Ones)

If ATAOS is selected by programming the appropriate global register, an all ones signal will be output to RPOS for each channel that experiences a SRLOS condition.  If SLOS does not occur, the ATAOS will remain inactive until a SRLOS on a given channel occurs.  A simplified block diagram of the ATAOS function is shown in Figure 11.

**FIGURE 11.  SIMPLIFIED BLOCK DIAGRAM OF THE ATAOS FUNCTION**
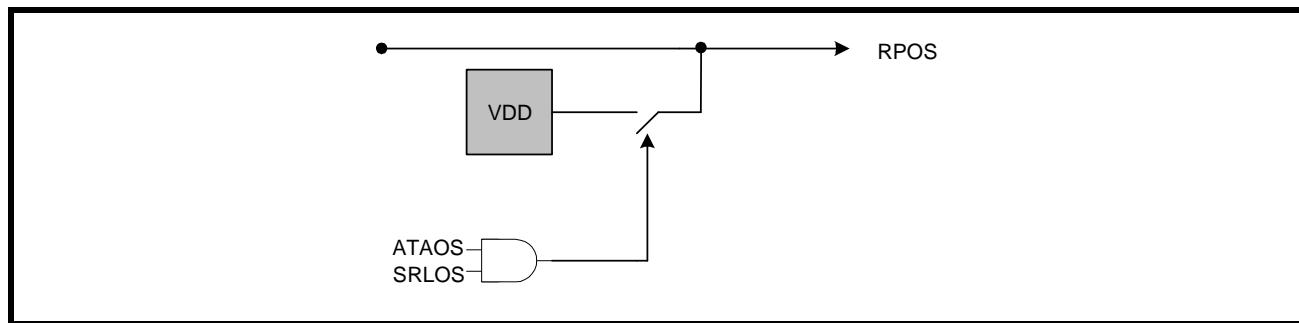

### 3.7.3    System Side LOS (SLOS)

The system side SLOS signal is an all zeros pattern sent to the RPOS output pin. This diagnostic pattern is created by pulling RPOS "Low" for the duration it's enabled.

**FIGURE 12.  SYSTEM SIDE SLOS RECEIVE OUTPUT**

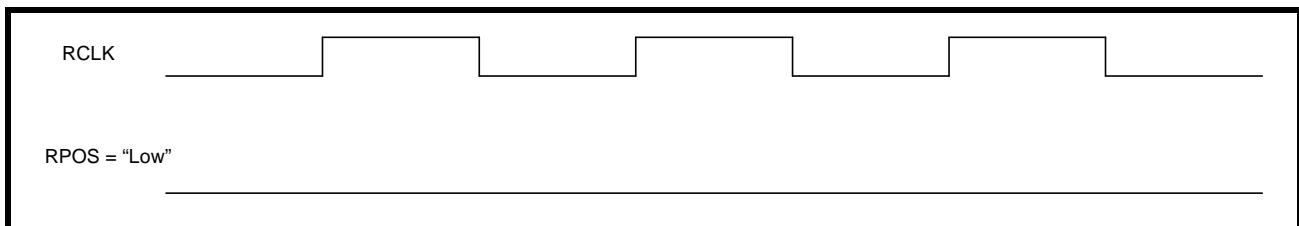

### 3.8    System Side SPRBS Receive Output

The system side SPRBS/SQRSS signal is a Pseudo Random Bit Sequence or Quasi Random Bit Sequence with the following polynomials.

**TABLE 5: RANDOM BIT SEQUENCE POLYNOMIALS**

| RANDOM PATTERN | T1 | E1 |
|---|---|---|
| SQRSS | $2^{20} - 1$ | $2^{20} - 1$ |
| SPRBS | $2^{15} - 1$ | $2^{15} - 1$ |

### 3.9    Jitter Attenuator (If enabled in the Receive Path)

The receive jitter attenuator reduces phase and frequency jitter in the recovered clock if it is enabled.  The jitter attenuator uses a data FIFO (First In First Out) with a programmable depth of 32-bit or 64-bit.  If the LIU is used for line synchronization (loop timing systems), the JA should be enabled in the receive path.  When the Read and Write pointers of the FIFO are within 2-Bits of over-flowing or under-flowing, the bandwidth of the jitter attenuator is widened to track the short term input jitter, thereby avoiding data corruption.  When this condition occurs, the jitter attenuator will not attenuate input jitter until the Read/Write pointer's position is outside the 2-Bit window.  In T1 mode, the bandwidth of the JA is always set to 3Hz.  In E1 mode, the bandwidth is programmable to either 10Hz or 1.5Hz (1.5Hz automatically selects the 64-Bit FIFO depth).  The JA has a clock delay equal to ½ of the FIFO bit depth.

*NOTE:*  *If the LIU is used in a multiplexer/mapper application where stuffing bits are typically removed, the jitter attenuator can be placed in the transmit path to smooth out the gapped clock.  See the Transmit Section of this datasheet.*

### 3.10    HDB3/B8ZS Decoder

In single rail mode, RPOS can decode AMI or HDB3/B8ZS signals.  For E1 mode, HDB3 is defined as any block of 4 successive zeros replaced with 000V or B00V, so that two successive V pulses are of opposite polarity to prevent a DC component.  In T1 mode, 8 successive zeros are replaced with 000VB0VB.  If the HDB3/B8ZS decoder is selected, the receive path removes the V and B pulses so that the original data is output to RPOS.

#### 3.10.0.1    RPOS/RNEG/RCLK

The digital output data can be programmed to either single rail or dual rail formats.  Figure 13 is a timing diagram of a repeating "0011" pattern in single-rail mode.  Figure 14 is a timing diagram of the same fixed pattern in dual rail mode.

**FIGURE 13.  SINGLE RAIL MODE WITH A FIXED REPEATING "0011" PATTERN**

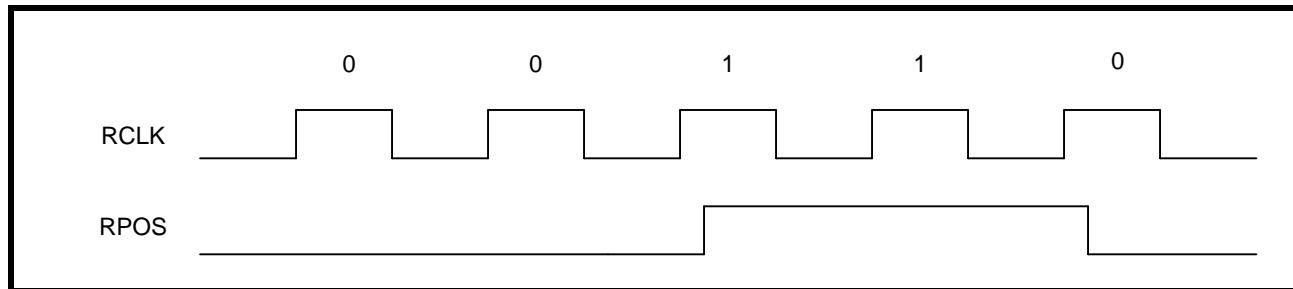

**FIGURE 14.  DUAL RAIL MODE WITH A FIXED REPEATING "0011" PATTERN**
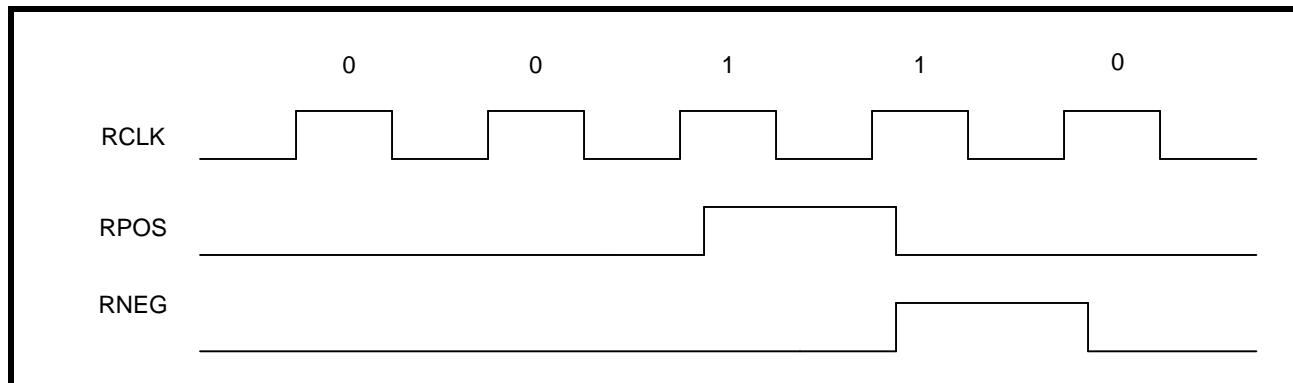

### 3.11    RxMUTE (Receiver LOS with Data Muting, Line Side Only)

The receive muting function can be selected by setting RxMUTE to "1" in the appropriate global register.  If selected, any channel that experiences an RLOS condition on the line side will automatically pull RPOS and RNEG "Low" to prevent data chattering.  If RLOS does not occur, the RxMUTE will remain inactive until an RLOS on a given channel occurs.  The default setting for RxMUTE is "0" which is disabled.  A simplified block diagram of the RxMUTE function is shown in Figure 15.

**FIGURE 15.  SIMPLIFIED BLOCK DIAGRAM OF THE RXMUTE FUNCTION**
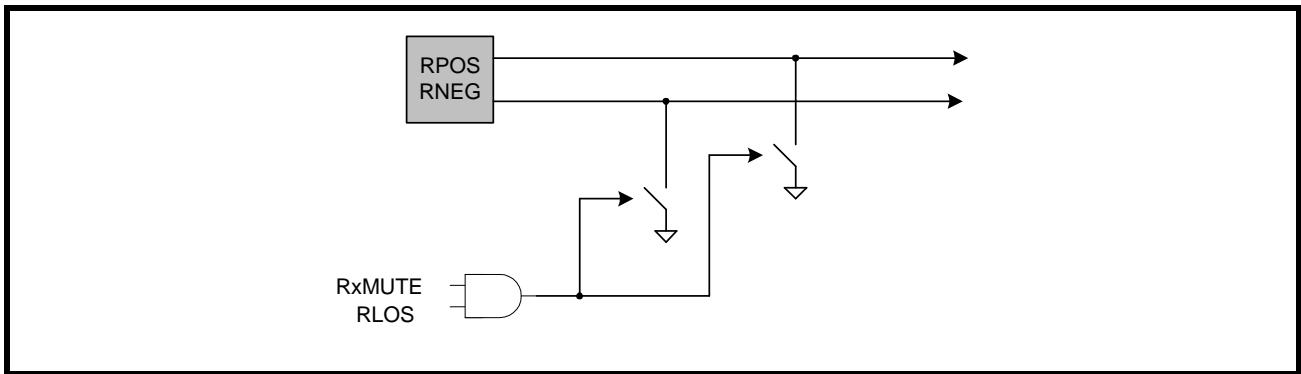

### 4.0   TRANSMIT PATH LINE INTERFACE

The transmit path of the XRT83VSH316 LIU consists of 16 independent T1/E1/J1 transmitters.  The following section describes the complete transmit path from TCLK/TPOS/TNEG inputs to TTIP/TRING outputs.  If any of the diagnostic detection features are used, the LIU must be set in Single Rail mode. Since, the transmit path has line side diagnostic generators, the part will automatically be placed in Singe Rail Mode whenever one of the diagnostic patterns is used. A simplified block diagram of the transmit and receive path is shown in Figure 16.

**FIGURE 16.  SIMPLIFIED BLOCK DIAGRAM OF THE TRANSMIT PATH**
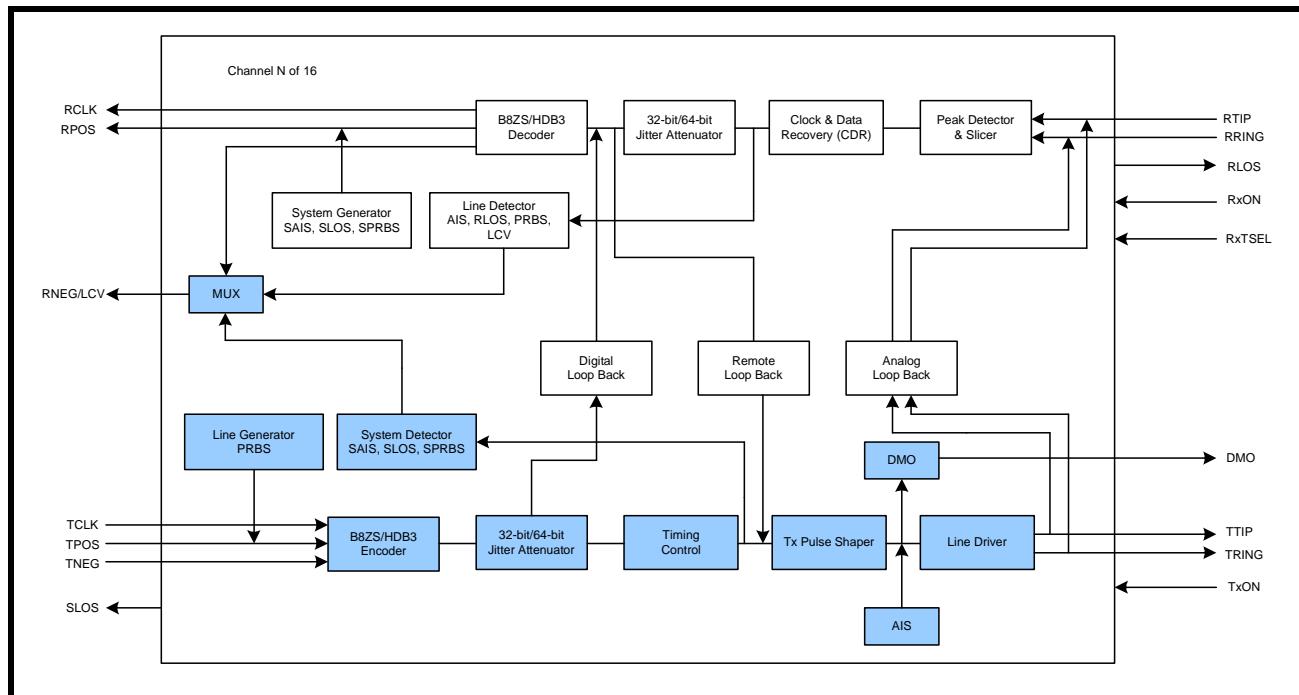

### 4.1　TCLK/TPOS/TNEG Digital Inputs

In dual rail mode, TPOS and TNEG are the digital inputs for the transmit path.  In single rail mode, TNEG has no function and can be left unconnected.  The XRT83VSH316 can be programmed to sample the inputs on either edge of TCLK.  By default, data is sampled on the falling edge of TCLK.  To sample data on the rising edge of TCLK, set TCLKE to "1" in the appropriate global register.  Figure 17 is a timing diagram of the transmit input data sampled on the falling edge of TCLK.   Figure 18 is a timing diagram of the transmit input data sampled on the rising edge of TCLK.  The timing specifications are shown in Table 6.

**FIGURE 17.  TRANSMIT DATA SAMPLED ON FALLING EDGE OF TCLK**

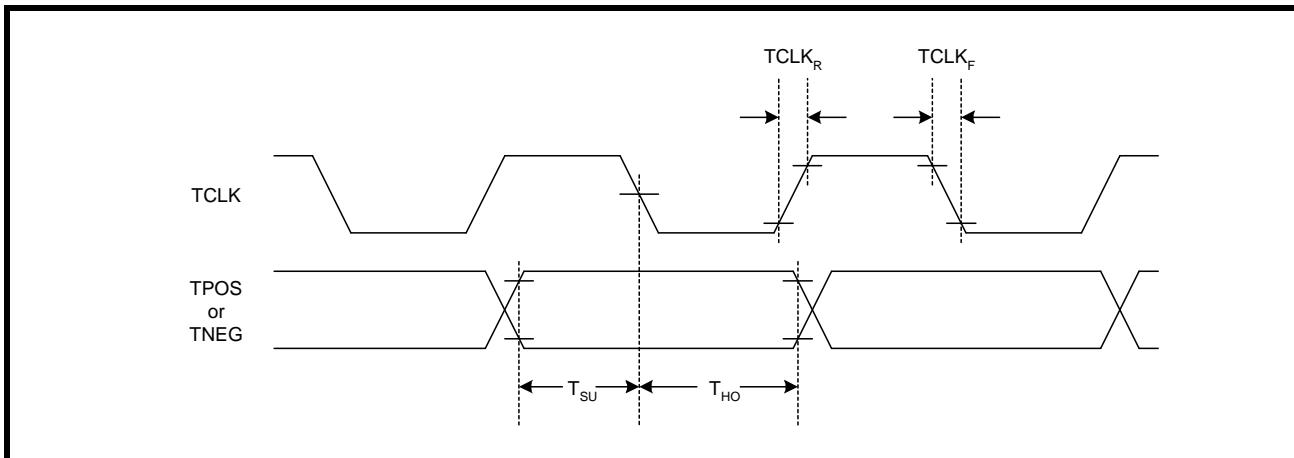

**FIGURE 18.  TRANSMIT DATA SAMPLED ON RISING EDGE OF TCLK**

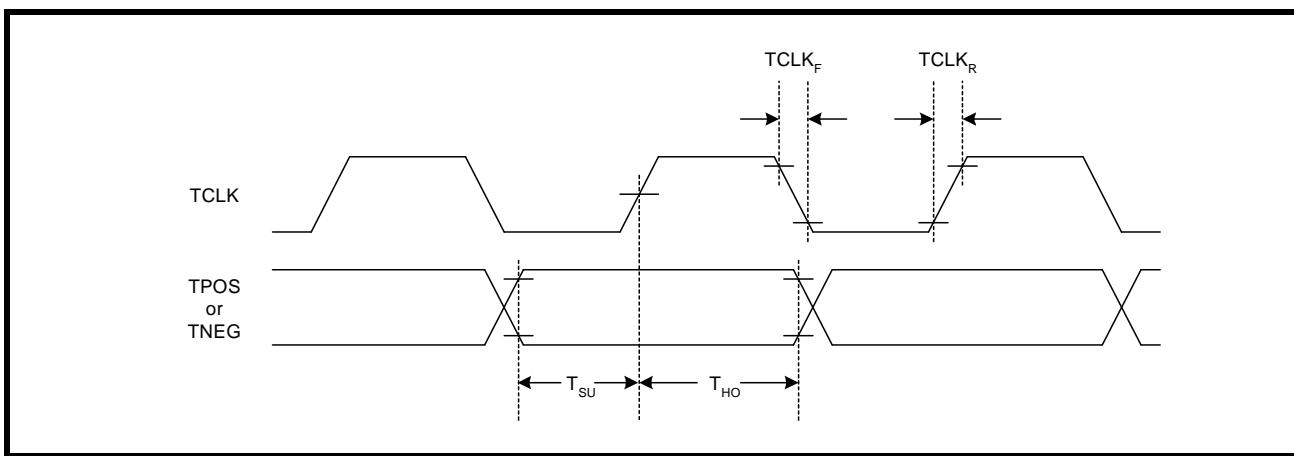

**TABLE 6: TIMING SPECIFICATIONS FOR TCLK/TPOS/TNEG**

| PARAMETER | SYMBOL | MIN | TYP | MAX | UNITS |
|---|---|---|---|---|---|
| TCLK Duty Cycle | $T_{CDU}$ | 30 | 50 | 70 | % |
| Transmit Data Setup Time | $T_{SU}$ | 50 | - | - | ns |
| Transmit Data Hold Time | $T_{HO}$ | 30 | - | - | ns |
| TCLK Rise Time (10% to 90%) | $TCLK_R$ | - | - | 40 | ns |
| TCLK Fall Time (90% to 10%) | $TCLK_F$ | - | - | 40 | ns |

**NOTE:**  *VDD=3.3V ±5%, VDDc=1.8V ±5%, $T_A$=25℃, Unless Otherwise Specified*

### 4.2    HDB3/B8ZS Encoder

In single rail mode, the LIU can encode the TPOS input signal to AMI or HDB3/B8ZS data.  In E1 mode and HDB3 encoding selected, any sequence with four or more consecutive zeros in the input will be replaced with 000V or B00V, where "B" indicates a pulse conforming to the bipolar rule and "V" representing a pulse violating the rule.  An example of HDB3 encoding is shown in Table 7.  In T1 mode and B8ZS encoding selected, an input data sequence with eight or more consecutive zeros will be replaced using the B8ZS encoding rule.  An example with Bipolar with 8 Zero Substitution is shown in Table 8.

**TABLE 7: EXAMPLES OF HDB3 ENCODING**

|  | **NUMBER OF PULSES BEFORE NEXT 4 ZEROS** |  |
|---|---|---|
| Input |  | 0000 |
| HDB3 (Case 1) | Odd | 000V |
| HDB3 (Case 2) | Even | B00V |

**TABLE 8: EXAMPLES OF B8ZS ENCODING**

| **CASE** | **PRECEDING PULSE** | **NEXT 8 BITS** |
|---|---|---|
| **Case 1** | | |
| Input | + | 00000000 |
| B8ZS |  | 000VB0VB |
| AMI Output | + | 000+-0-+ |
| **Case 2** | | |
| Input | - | 00000000 |
| B8ZS |  | 000VB0VB |
| AMI Output | - | 000-+0+- |

### 4.3    Jitter Attenuator (If enabled in the Transmit Path)

The XRT83VSH316 LIU is ideal for multiplexer or mapper applications where the network data crosses multiple timing domains.  As the higher data rates are de-multiplexed down into T1 or E1 data, stuffing bits are typically removed which can leave gaps in the incoming data stream. The transmit jitter attenuator can be enabled with a 32-Bit or 64-Bit FIFO that is used to smooth the gapped clock into a steady T1 or E1 output. The maximum gap width of the 16-Channel LIU is shown in Table 9.

**TABLE 9: MAXIMUM GAP WIDTH FOR MULTIPLEXER/MAPPER APPLICATIONS**

| **FIFO DEPTH** | **MAXIMUM GAP WIDTH** |
|---|---|
| 32-Bit | 20 UI |
| 64-Bit | 50 UI |

*NOTE:  If the LIU is used in a loop timing system, the jitter attenuator can be placed in the receive path.  See the Receive Section of this datasheet.*

#### 4.4 Transmit Diagnostic Pattern Generation

The transmit path has the ability to generate diagnostic patterns to the line side interface on the TTip/TRing output pins (Single Rail Mode Only). The LIU can generate an All Ones (AIS) or PRBS/QRSS (PRBS) signal.

#### 4.4.1 Line Side AIS (Transmit All Ones)

The XRT83VSH316 has the ability to transmit all ones on a per channel basis by programming the appropriate channel register. The AIS signal is generated on TTip and TRing.

**FIGURE 19. TAOS (TRANSMIT ALL ONES)**

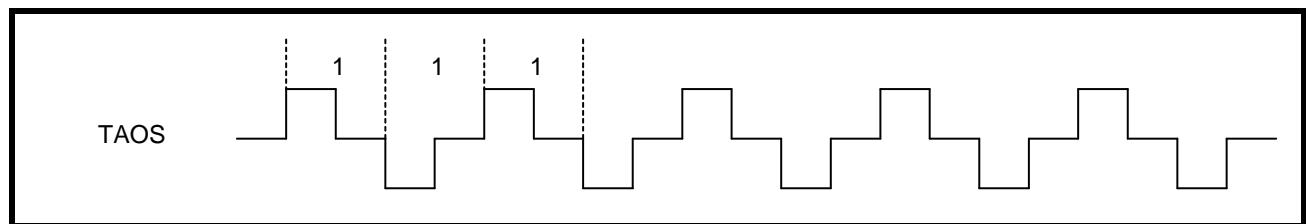

#### 4.4.2 ATAOS (Automatic Transmit All Ones)

If ATAOS is selected by programming the appropriate global register, an AMI all ones signal will be transmitted for each channel that experiences an RLOS condition.  If RLOS does not occur, the ATAOS will remain inactive until an RLOS on a given channel occurs.  A simplified block diagram of the ATAOS function is shown in Figure 20.

**FIGURE 20. SIMPLIFIED BLOCK DIAGRAM OF THE ATAOS FUNCTION**

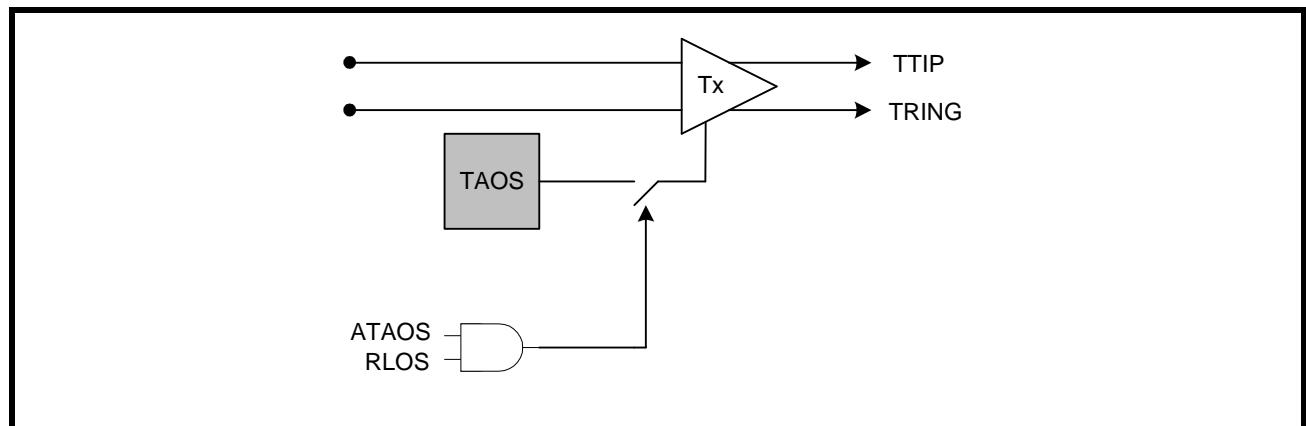

#### 4.4.3 Line Side PRBS/QRSS (Pseudo/Quasi Random Bit Sequence)

The XRT83VSH316 can transmit a PRBS/QRSS random sequence to a remote location from the TTip/TRing output pins. To select PRBS or QRSS, see the register map for programming details.  The polynomial is shown in Table 10.

**TABLE 10: RANDOM BIT SEQUENCE POLYNOMIALS**

| RANDOM PATTERN | T1 | E1 |
|---|---|---|
| QRSS | $2^{20}$ - 1 | $2^{20}$ - 1 |
| PRBS | $2^{15}$ - 1 | $2^{15}$ - 1 |

### 4.5    Transmit Diagnostic Pattern Detection

The transmit path has the ability to detect diagnostic patterns on the system side interface from the TPOS input pin (Single Rail Mode Only). The LIU can detect an All Ones (SAIS), Loss of Signal (RLOS), or PRBS/QRSS (SPRBS).

#### 4.5.1    SLOS (System Loss of Signal)

The XRT83VSH316 supports both G.775 or ETSI-300-233 RLOS detection scheme.

In G.775 mode, LOS is declared when the received signal is less than 375mV for 32 consecutive pulse periods (typical). The device clears LOS when the receive signal achieves 12.5% ones density with no more than 15 consecutive zeros in a 32 bit sliding window and the signal level exceeds 425mV (typical).

In ETSI-300-233 mode the device declares LOS when the input level drops below 375mV (typical) for more than 2048 pulse periods (1msec).

The device exits LOS when the input signal exceeds 425mV (typical) and has transitions for more than 32 pulse periods with 12.5% ones density with no more than 15 consecutive zero's in a 32 bit sliding window.

In T1 mode RLOS is declared when the received signal is less than 320mV for 175 consecutive pulse period (typical). The device clears RLOS when the receive signal achieves 12.5% ones density with no more than 100 consecutive zeros in a 128 bit sliding window and the signal level exceeds 425mV (typical).

#### 4.5.2    SYS_EXLOS (System Extended Loss of Signal)

By enabling the system extended loss of signal by programming the appropriate channel register, the digital SLOS is extended to count 4,096 consecutive zeros before declaring SLOS in T1 and E1 mode. By default, EXLOS is disabled and SLOS operates in normal mode.

#### 4.5.3    SAIS (System Alarm Indication Signal)

The XRT83VSH316 adheres to the ITU-T G.775 specification for an all ones pattern. The alarm indication signal is set to "1" if an all ones pattern (at least 99.9% ones density) is present for T, where T is 3ms to 75ms in T1 mode. AIS will clear when the ones density is not met within the same time period T. In E1 mode, the AIS is set to "1" if the incoming signal has 2 or less zeros in a 512-bit window. AIS will clear when the incoming signal has 3 or more zeros in the 512-bit window.

### 4.6    Transmit Pulse Shaper and Filter

If TCLK is not present, pulled "Low", or pulled "High" the transmitter outputs at TTIP/TRING will automatically send an all ones or an all zero signal to the line by programming the appropriate global register.  By default, the transmitters will send all zeros.  To send all ones, the TCLKCNL bit must be set "High" in the appropriate global register.

#### 4.6.1    T1 Short Haul Line Build Out (LBO)

The short haul transmitter output pulses are generated using a 7-Bit internal DAC (6-Bit plus the MSB sign bit). The line build out can be set to interface to five different ranges of cable attenuation by programming the appropriate channel register.  The pulse shape is divided into eight discrete time segments which are set to fixed values to comply with the pulse template.  The short haul LBO settings are shown in Table 11.

**TABLE 11: SHORT HAUL LINE BUILD OUT**

| LBO SETTING EQC[4:0] | RANGE OF CABLE ATTENUATION |
|---|---|
| 08h (01000) | 0 - 133 Feet |
| 09h (01001) | 133 - 266 Feet |
| 0Ah (01010) | 266 - 399 Feet |
| 0Bh (01011) | 399 - 533 Feet |
| 0Ch (01100) | 533 - 655 Feet |

#### 4.6.2    Arbitrary Pulse Generator For T1 and E1

The arbitrary pulse generator divides the pulse into eight individual segments.  Each segment is set by a 7-Bit binary word by programming the appropriate channel register.  This allows the system designer to set the overshoot, amplitude, and undershoot for a unique line build out.  The MSB (bit 7) is a sign-bit.  If the sign-bit is set to "0", the segment will move in a positive direction relative to a flat line (zero) condition.  If this sign-bit is set to "1", the segment will move in a negative direction relative to a flat line condition.  The resolution of the DAC is typically 45mV per LSB.  Thus, writing 7-bit = 1111111 will clamp the output at either voltage rail corresponding to a maximum amplitude.  A pulse with numbered segments is shown in Figure 21.

**FIGURE 21.  ARBITRARY PULSE SEGMENT ASSIGNMENT**

| Segment | Register |
|---|---|
| 1 | 0xN08 |
| 2 | 0xN09 |
| 3 | 0xN0A |
| 4 | 0xN0B |
| 5 | 0xN0C |
| 6 | 0xN0D |
| 7 | 0xN0E |
| 8 | 0xN0F |
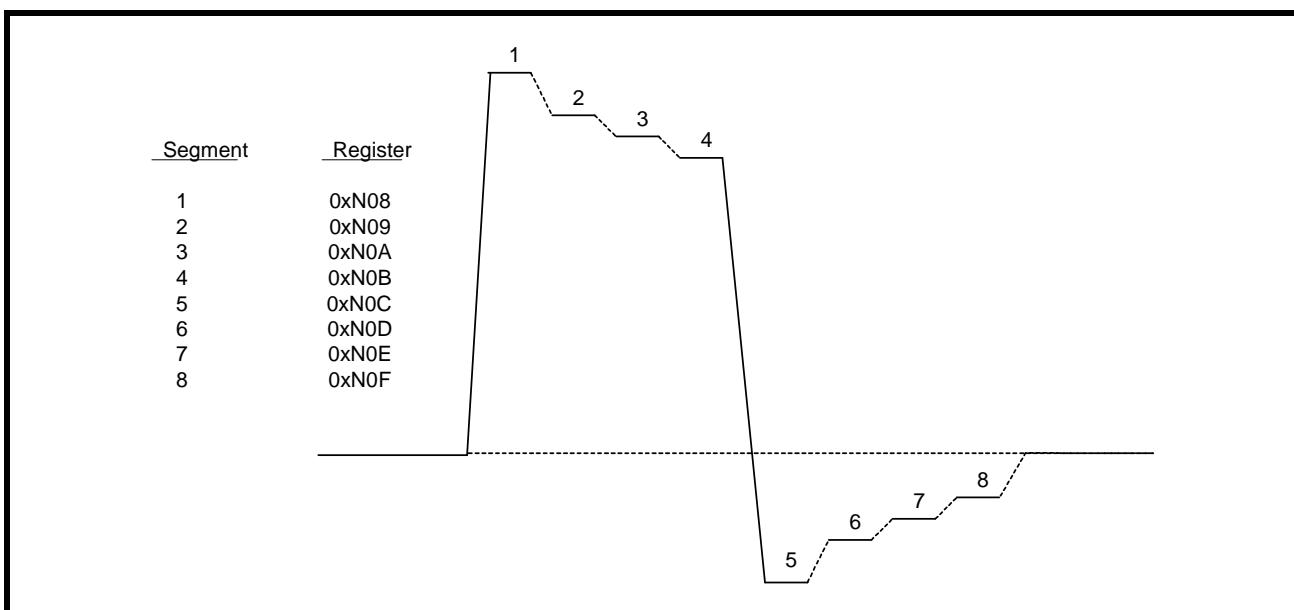

**NOTE:**   *By default, the arbitrary segments are programmed to 0x00h.  The transmitter outputs will result in an all zero pattern to the line interface.*

### 4.6.3    Setting Registers to select an Aribtrary Pulse

For T1: Address:0xN00 hex, bits D[4:0]

For E1: Address: 0xN03 hex, bit D3

To program the transmit output pulse, once the arbitrary pulse has been selected, write the appropriate values into the segment registers in Table 12.

The transmit output pulse is divided into eight individual segments. Segment 1 corresponds to the beginning of the pulse and segment 8 to the end of the pulse. The value for each segment can be programed individually through a corresponding 8-bit register. In normal operation, i.e., non-arbitrary mode, codes are stored in an internal ROM and are used to generate the pulse shape, as shown in Table 12. Typical ROM values are given below in Hex.

**TABLE 12: TYPICAL ROM VALUES**

| LINE DISTANCE | SEGMENT # | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| FEET | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| 0 - 133 | 22 | 1F | 1E | 1D | 4F | 48 | 44 | 41 |
| 133 - 266 | 25 | 21 | 20 | 1E | 52 | 4C | 47 | 43 |
| 266 - 399 | 2C | 23 | 21 | 20 | 57 | 4C | 47 | 43 |
| 399 - 525 | 32 | 25 | 23 | 22 | 66 | 52 | 47 | 44 |
| 525 - 655 | 3D | 27 | 24 | 22 | 70 | 57 | 49 | 44 |
| | | | | | | | | |
| E1 | 24 | 1E | 1E | 1E | 00 | 00 | 00 | 00 |

*NOTE:  The same register bank (eight registers in total) holds the values for any given line length. In other words , the user can not load all the desired values for all the line lengths into the device at one time. If the line length is changed, new codes must be loaded into the register banks.*

### 4.7    DMO (Digital Monitor Output, Line Side Only)

The driver monitor circuit is used to detect transmit driver failures by monitoring the activities at TTip/TRing outputs.  Driver failure may be caused by a short circuit in the primary transformer or system problems at the transmit inputs. If the transmitter of a channel has no output for more than 128 clock cycles, DMO is set "High" until a valid transmit pulse is detected. If the DMO interrupt is enabled, the change in status of DMO will cause the interrupt pin to go "Low". Once the status register is read, the interrupt pin will return "High" and the status register will be reset (RUR).

### 4.8 Line Termination (TTip/TRing)

The output stage of the transmit path generates standard return-to-zero (RZ) signals to the line interface for T1/ E1/J1 twisted pair or E1 coaxial cable. The physical interface is optimized by placing the terminating impedance inside the LIU. This allows one bill of materials for all modes of operation reducing the number of external components necessary in system design. The transmitter outputs only require one DC blocking capacitor of 0.68µF. For redundancy applications (or simply to tri-state the transmitters), set TxTSEL to a "1" in the appropriate channel register. A typical transmit interface is shown in Figure 22.

**FIGURE 22. TYPICAL CONNECTION DIAGRAM USING INTERNAL TERMINATION**
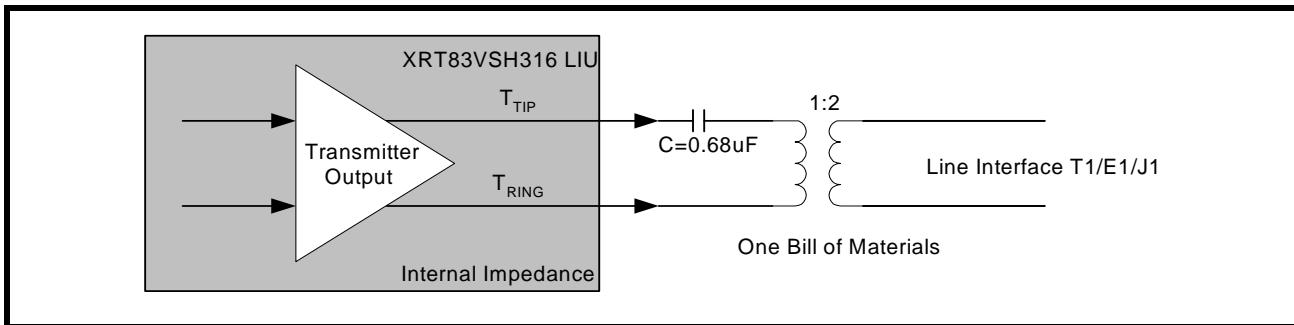

### 5.0 T1/E1 APPLICATIONS

This application section describes common T1/E1 system considerations along with the various loop back modes available in the LIU.

### 5.1 Loopback Diagnostics

The XRT83VSH316 supports several loopback modes for diagnostic testing. The following section describes the local analog loopback, remote loopback, digital loopback, and dual loopback modes.

### 5.1.1 Local Analog Loopback

With local analog loopback activated, the transmit output data at TTip/TRing is internally looped back to the analog inputs at RTip/RRing. External inputs at RTip/RRing are ignored while valid transmit output data continues to be sent to the line. A simplified block diagram of local analog loopback is shown in Figure 23.

**FIGURE 23. SIMPLIFIED BLOCK DIAGRAM OF LOCAL ANALOG LOOPBACK**
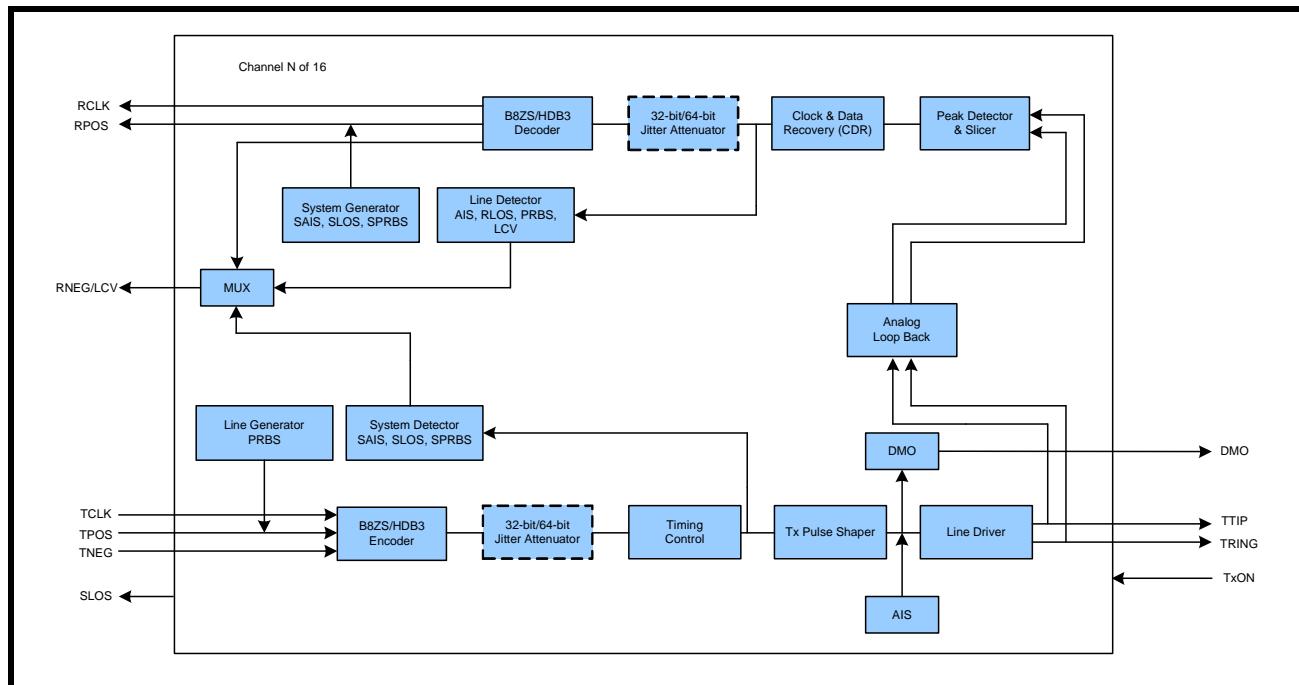

### 5.1.2    Remote Loopback

With remote loopback activated, the receive input data at RTip/RRing is internally looped back to the transmit output data at TTip/TRing. The transmit input data at TCLK/TPOS/TNEG are ignored while valid receive output data continues to be sent to the system. A simplified block diagram of remote loopback is shown in Figure 24.

**FIGURE 24.  SIMPLIFIED BLOCK DIAGRAM OF REMOTE LOOPBACK**
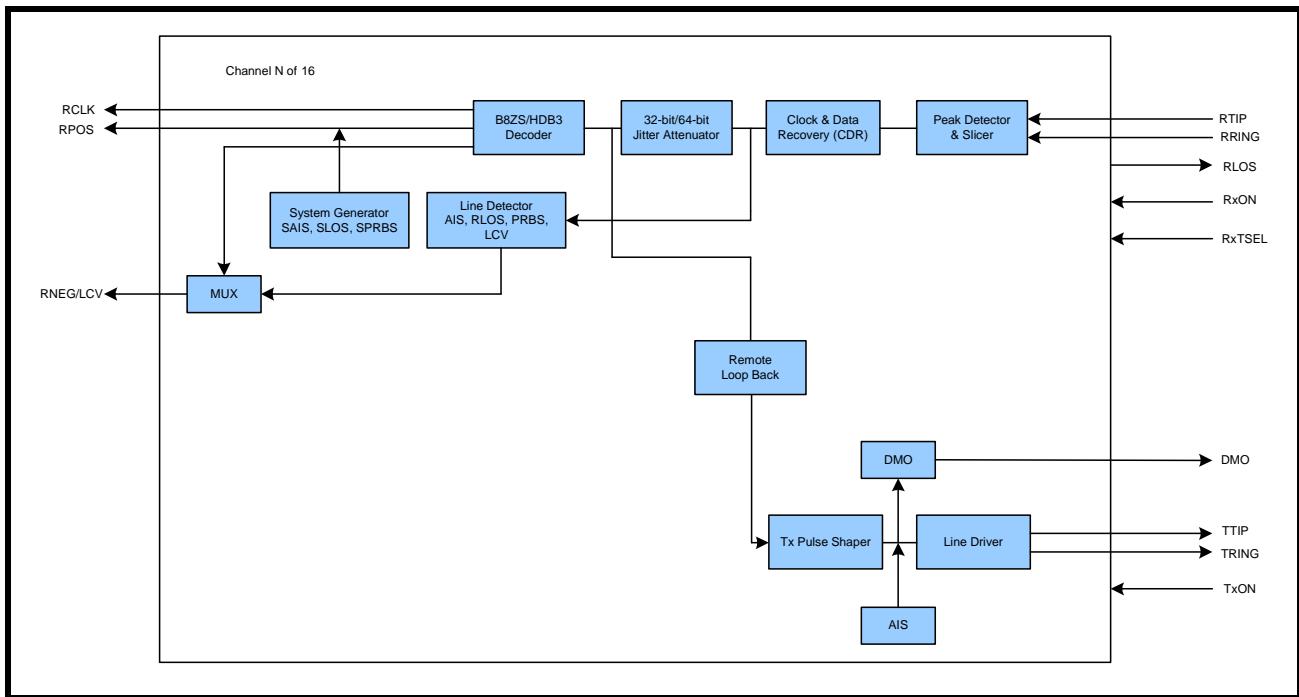

### 5.1.3    Digital Loopback

With digital loopback activated, the transmit input data at TCLK/TPOS/TNEG is looped back to the receive output data at RCLK/RPOS/RNEG after the Transmit Jitter Attenuator (if enabled).  The receive input data at RTIP/RRING is ignored while valid transmit output data continues to be sent to the line.  A simplified block diagram of digital loopback is shown in Figure 25.

**FIGURE 25.  SIMPLIFIED BLOCK DIAGRAM OF DIGITAL LOOPBACK**
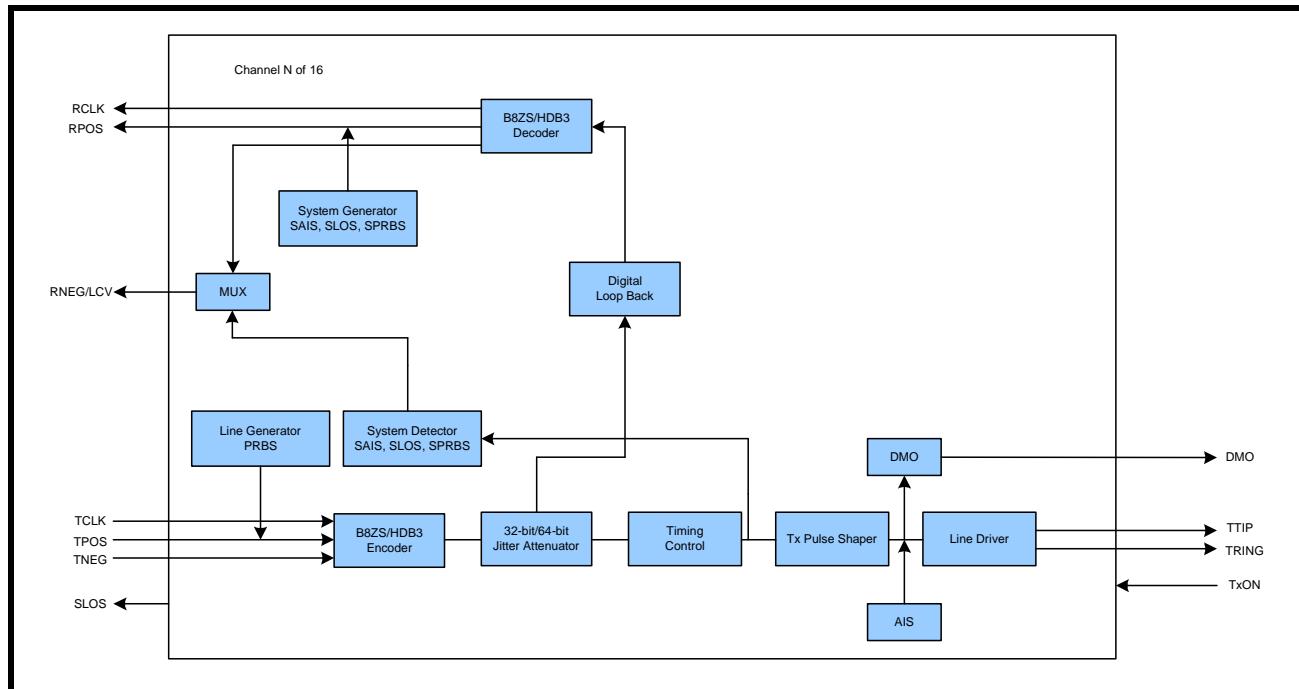

### 5.1.4   Dual Loopback

With dual loopback activated, the remote loopback is combined with the digital loopback. A simplified block diagram of dual loopback is shown in Figure 26.

**FIGURE 26.  SIMPLIFIED BLOCK DIAGRAM OF DUAL LOOPBACK**
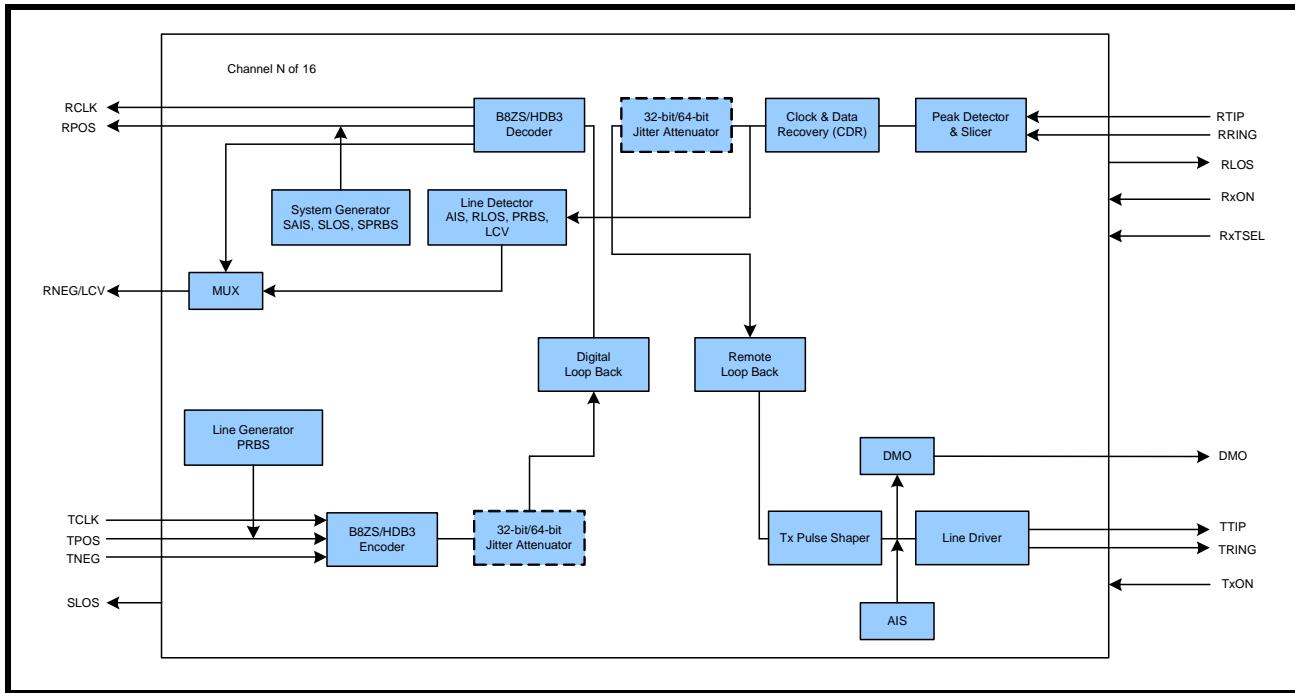

### 5.2    84-Channel T1/E1 Multiplexer/Mapper Applications

The XRT83VSH316 has the capability of providing the necessary chip selects for multiple 16-channel LIU devices. The LIU is responsible for selecting itself, up to 5 additional LIU devices, or all 6 devices simultaneously for permitting access to internal registers. The state of the chip select output pins is determined by a chip select decoder controlled by the 3 MSBs of the address bus ADDR[12:10]. Only one LIU (Master) requires the ADDR[12:10]. The other 5 LIU devices use the 10 LSBs for the direct address bus ADDR[9:0]. Figure 27 is a simplified block diagram of connecting six 16-channel LIU devices for 84-channel applications. Selection of the chip select outputs using ADDR[12:10] is shown in Table 13.

**FIGURE 27.  SIMPLIFIED BLOCK DIAGRAM OF AN 84-CHANNEL APPLICATION**

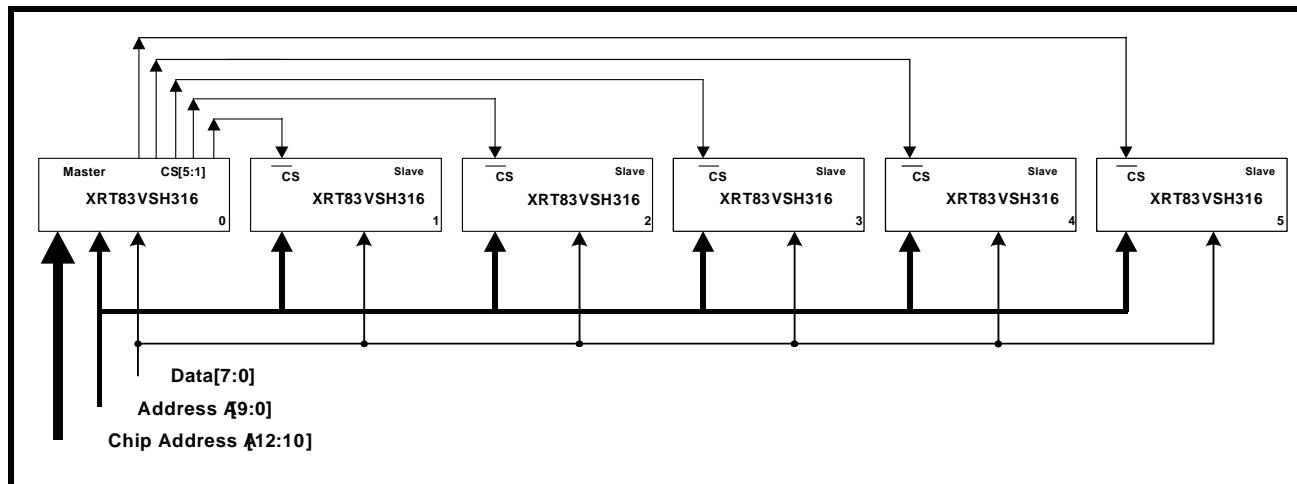

**TABLE 13: CHIP SELECT ASSIGNMENTS**

| ADDR[12:10] | ACTIVE CHIP SELECT |
|---|---|
| 0h (000) | Current Device (Master) |
| 1h (001) | Chip 1 |
| 2h (010) | Chip 2 |
| 3h (011) | Chip 3 |
| 4h (100) | Chip 4 |
| 5h (101) | Chip 5 |
| 6h (110) | Reserved |
| 7h (111) | All Devices Active |

### 5.3     Line Card Redundancy

Telecommunication system design requires signal integrity and reliability. When a T1/E1 primary line card has a failure, it must be swapped with a backup line card while maintaining connectivity to a backplane without losing data. System designers can achieve this by implementing common redundancy schemes with the XRT83VSH316 LIU. EXAR offers features that are tailored to redundancy applications while reducing the number of components and providing system designers with solid reference designs.

**RLOS/SLOS and DMO**

If an RLOS/SLOS or DMO condition occurs, the XRT83VSH316 reports the alarm to the individual status registers on a per channel basis. However, for redundancy applications, an RLOS/SLOS or DMO alarm can be used to initiate an automatic switch to the back up card. For this application, three global pins RLOS, SLOS, and DMO are used to indicate that one of the 16-channels has a LOS or DMO condition.

**Typical Redundancy Schemes**

- 1:1 One backup card for every primary card (Facility Protection)

- 1+1 One backup card for every primary card (Line Protection)

- ·N+1 One backup card for N primary cards

### 5.3.1     1:1 and 1+1 Redundancy Without Relays

The 1:1 facility protection and 1+1 line protection have one backup card for every primary card.  When using 1:1 or 1+1 redundancy, the backup card has its transmitters tri-stated and its receivers in high impedance.  This eliminates the need for external relays and provides one bill of materials for all interface modes of operation. For 1+1 line protection, the receiver inputs on the backup card have the ability to monitor the line for bit errors while in high impedance.  The transmit and receive sections of the LIU device are described separately.

### 5.3.2     Transmit Interface with 1:1 and 1+1 Redundancy

The transmitters on the backup card should be tri-stated.  Select the appropriate impedance for the desired mode of operation, T1/E1/J1.  A 0.68uF capacitor is used in series with TTIP for blocking DC bias.  See Figure 28. for a simplified block diagram of the transmit section for a 1:1 and 1+1 redundancy.

**FIGURE 28.  SIMPLIFIED BLOCK DIAGRAM OF THE TRANSMIT INTERFACE FOR 1:1 AND 1+1 REDUNDANCY**
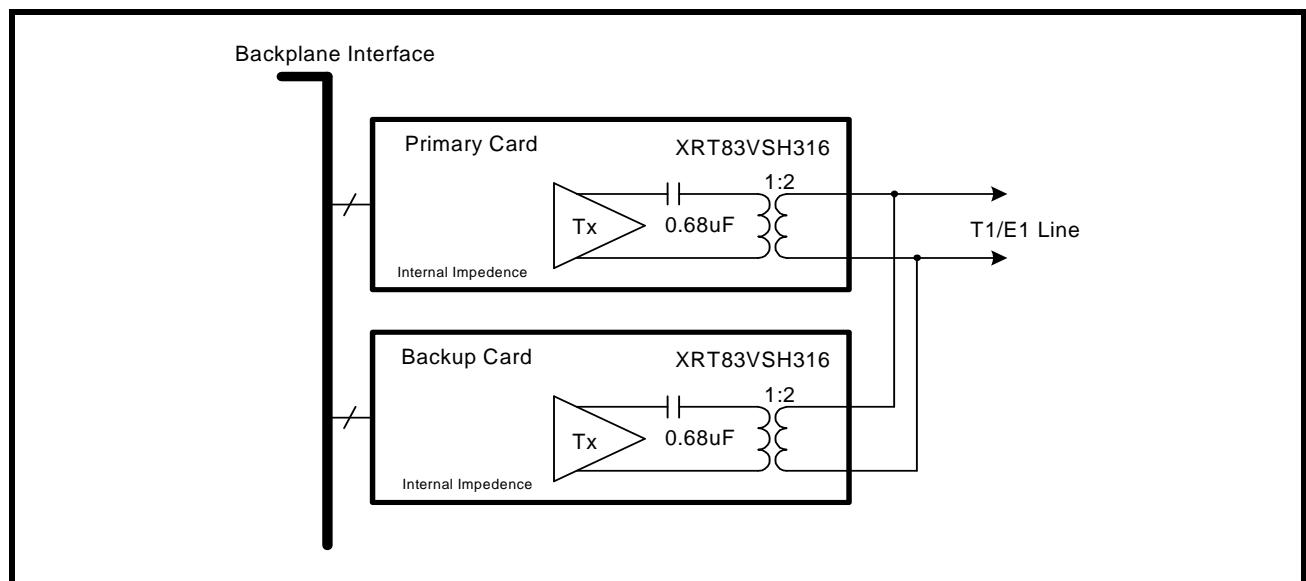

### 5.3.3 Receive Interface with 1:1 and 1+1 Redundancy

The receivers on the backup card should be programmed for "High" impedance. Since there is no external resistor in the circuit, the receivers on the backup card will not load down the line interface. This key design feature eliminates the need for relays and provides one bill of materials for all interface modes of operation. Select the impedance for the desired mode of operation, T1/E1/J1. To swap the primary card, set the backup card to internal impedance, then the primary card to "High" impedance. See Figure 29. for a simplified block diagram of the receive section for a 1:1 redundancy scheme.

**FIGURE 29. SIMPLIFIED BLOCK DIAGRAM OF THE RECEIVE INTERFACE FOR 1:1 AND 1+1 REDUNDANCY**

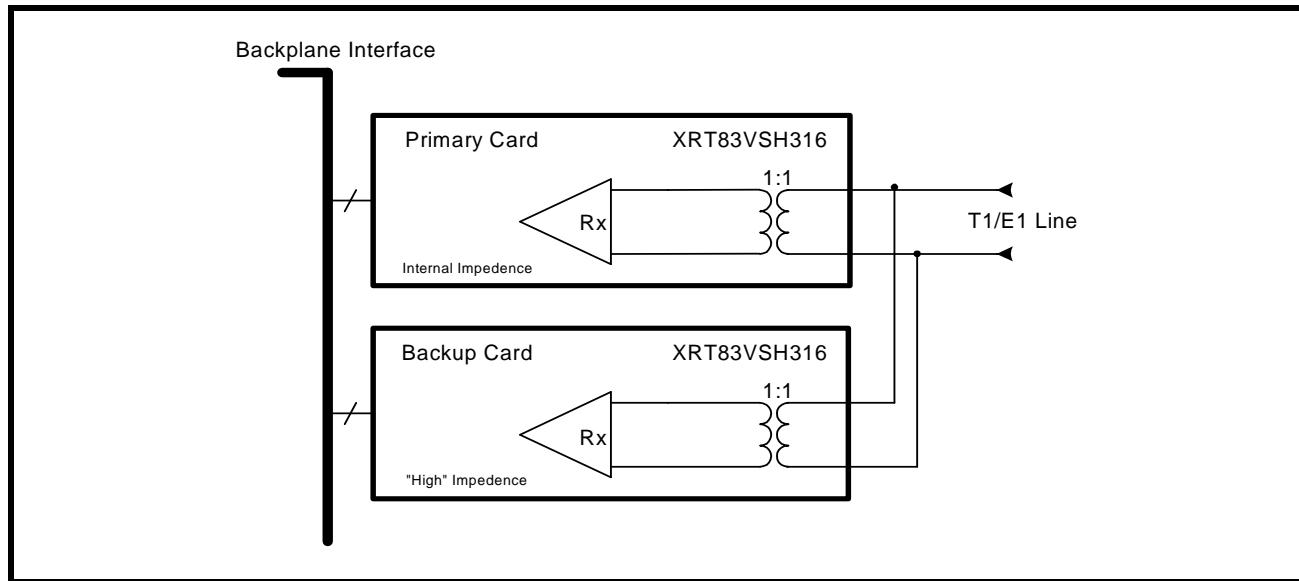

### 5.3.4 N+1 Redundancy Using External Relays

N+1 redundancy has one backup card for N primary cards. Due to impedance mismatch and signal contention, external relays are necessary when using this redundancy scheme. The relays create complete isolation between the primary cards and the backup card. This allows all transmitters and receivers on the primary cards to be configured in internal impedance, providing one bill of materials for all interface modes of operation. The transmit and receive sections of the LIU device are described separately.

### 5.3.5 Transmit Interface with N+1 Redundancy

For N+1 redundancy, the transmitters on all cards should be programmed for internal impedance. The transmitters on the backup card do not have to be tri-stated. To swap the primary card, close the desired relays, and tri-state the transmitters on the failed primary card. A 0.68uF capacitor is used in series with TTIP for blocking DC bias. See Figure 30 for a simplified block diagram of the transmit section for an N+1 redundancy scheme.

**FIGURE 30. SIMPLIFIED BLOCK DIAGRAM OF THE TRANSMIT INTERFACE FOR N+1 REDUNDANCY**
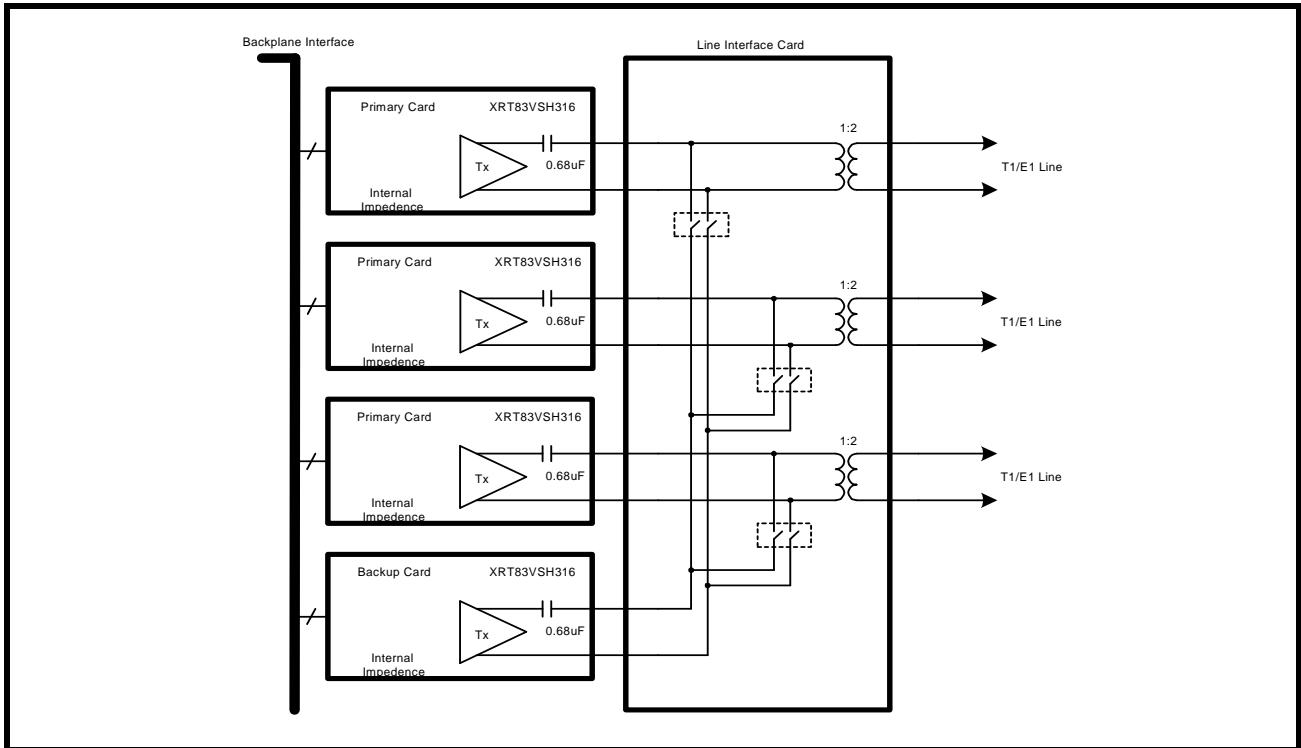

### 5.3.6    Receive Interface with N+1 Redundancy

For N+1 redundancy, the receivers on the primary cards should be programmed for internal impedance.  The receivers on the backup card should be programmed for "High" impedance mode.  To swap the primary card, set the backup card to internal impedance, then the primary card to "High" impedance.  See Figure 31 for a simplified block diagram of the receive section for a N+1 redundancy scheme.

**FIGURE 31.  SIMPLIFIED BLOCK DIAGRAM OF THE RECEIVE INTERFACE FOR N+1 REDUNDANCY**
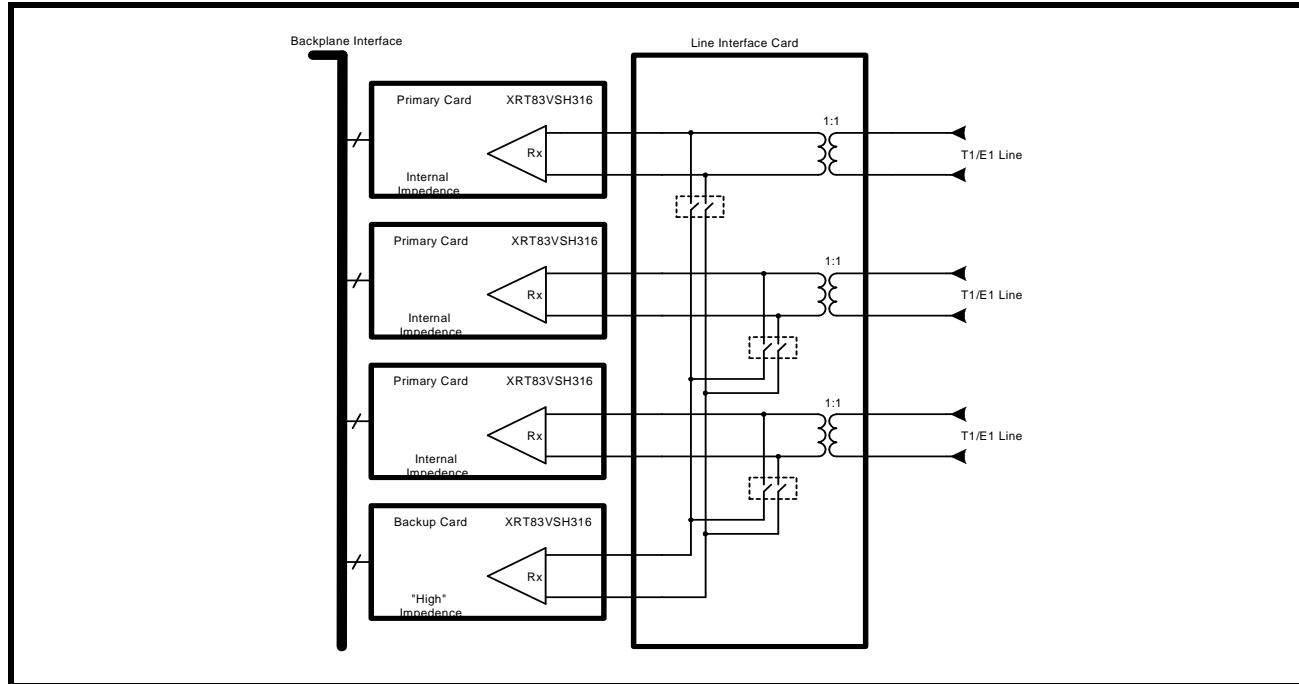

### 5.4    Power Failure Protection

For 1:1 or 1+1 line card redundancy in T1/E1 applications, power failure could cause a line card to change the characteristics of the line impedance, causing a degradation in system performance.  The XRT83VSH316 was designed to ensure reliability during power failures.  The LIU has patented high impedance circuits that allow the receiver inputs and the transmitter outputs to be in "High" impedance when the LIU experiences a power failure or when the LIU is powered off.

*NOTE:  For power failure protection, a transformer must be used to couple to the line interface.  See the TAN-56 application note for more details.*

### 5.5    Overvoltage and Overcurrent Protection

Physical layer devices such as LIUs that interface to telecommunications lines are exposed to overvoltage transients posed by environmental threats.  An Overvoltage transient is a pulse of energy concentrated over a small period of time, usually under a few milliseconds.  These pulses are random and exceed the operating conditions of CMOS transceiver ICs.  Electronic equipment connecting to data lines are susceptible to many forms of overvoltage transients such as lightning, AC power faults and electrostatic discharge (ESD).  There are three important standards when designing a telecommunications system to withstand overvoltage transients.

- UL1950 and FCC Part 68

- Telcordia (Bellcore) GR-1089

- ITU-T K.20, K.21 and K.41

*NOTE:  For a reference design and performance, see the TAN-58 application note for more details.*

### 5.6    Non-Intrusive Monitoring

In non-intrusive monitoring applications, the transmitters are shut off by setting TxON "Low".  The receivers must be actively receiving data without interfering with the line impedance.  The XRT83VSH316's internal termination ensures that the line termination meets T1/E1 specifications for 75Ω, 100Ω or 120Ω while monitoring the data stream.  System integrity is maintained by placing the non-intrusive receiver in "High" impedance, equivalent to that of a 1+1 redundancy application.  A simplified block diagram of non-intrusive monitoring is shown in Figure 32.

**FIGURE 32.  SIMPLIFIED BLOCK DIAGRAM OF A NON-INTRUSIVE MONITORING APPLICATION**
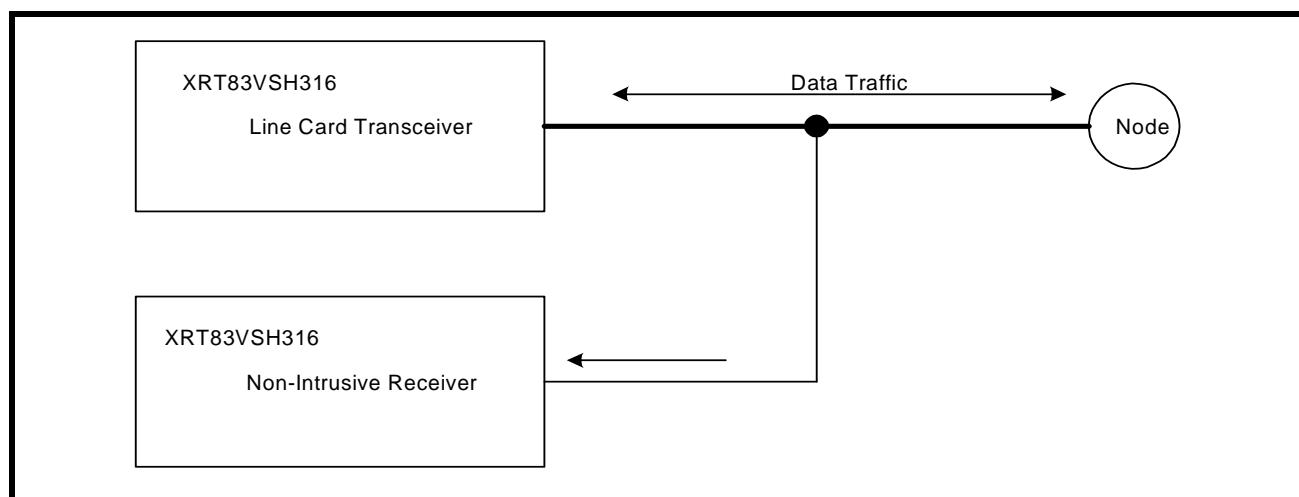

## 5.7 Analog Board Continuity Check

This test verifies the per-channel continuity from the Line Side of TIP and RING for both the transmitters and receivers, through the transformers on the assembly and LIU. Inside the LIU, a MUX and Control logic using TMS and TCK as reset and clock, successively connect each TIP and RING on the XRT83VSH316 side to two Analog Test Pins, (ATP_TIP and ATP_RING). Simplified block and timing diagrams are shown in Figure 33 and Figure 34.

**FIGURE 33. ATP TESTING BLOCK DIAGRAM**

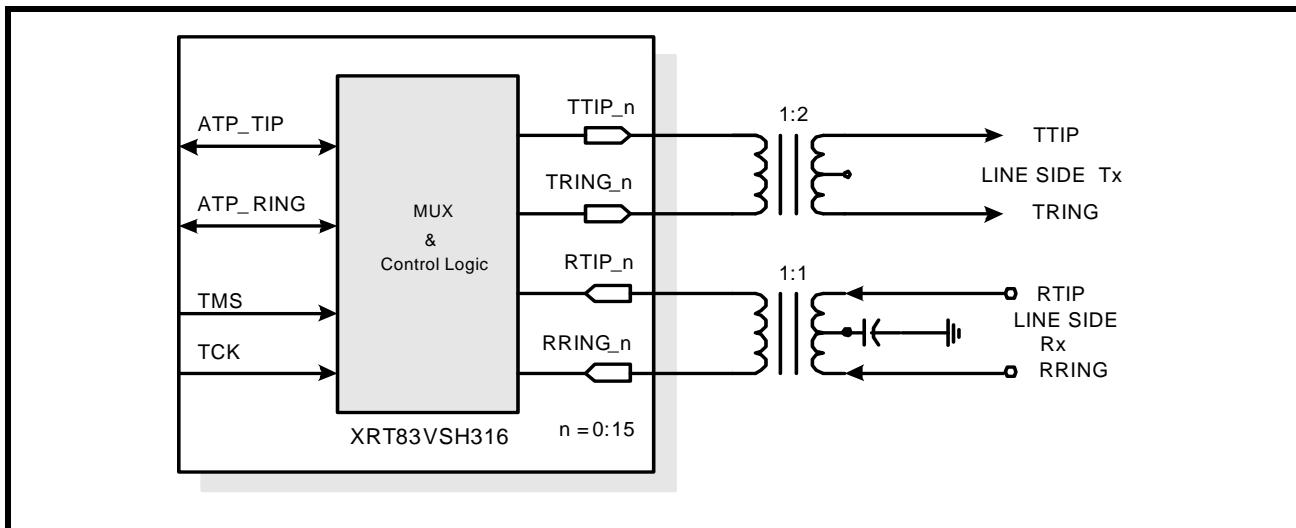

**FIGURE 34. TIMING DIAGRAM FOR ATP TESTING**

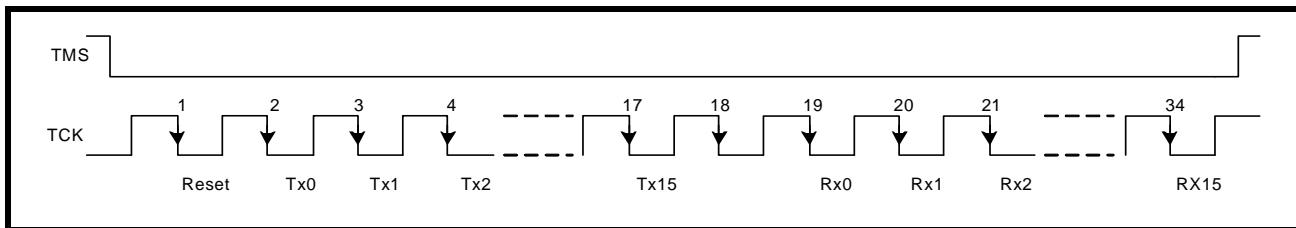

## 5.7.1 Transmitter TTIP and TRING Testing

Testing of each channel must be done in sequence. With a clock signal applied to TCK, Setting TMS to "0" will begin the test sequence. On the falling edge of the 1st clock pulse after TMS is set to "0", the sequence will reset as shown in Figure 34 above. On the 2nd falling clock edge the signal on ATP_TIP and ATP_RING will be TTIP_0 and TRING_0, respectively. On the falling edge of the 19th clock pulse the signal on ATP_TIP and ATP_RING will be connected to RTIP_0 and RRING_0, respectively. After the 34th clock pulse TMS can be returned to a "1" and all channels will return to their normal state.

## 6.0   MICROPROCESSOR INTERFACE

The microprocessor interface can be accessed through a Standard Peripheral Interface (Serial SPI) or Standard Parallel Microprocessor Interface. By default, the parallel interface is selected. To use the SPI interface, the SER/$\overline{PAR}$ pin must be pulled "High".

### 6.1   *SPI Serial Peripheral Interface Block*

The serial microprocessor uses a standard 3-pin serial port with $\overline{CS}$, SCLK, and SDI for programming the LIU. Optional pins such as SDO, $\overline{INT}$, and $\overline{RESET}$ allow the ability to read back contents of the registers, monitor the LIU via an interrupt pin, and reset the LIU to its default configuration by pulling reset "Low" for more than 10µS. A simplified block diagram of the Serial Microprocessor is shown in Figure 35.

**FIGURE 35.  SIMPLIFIED BLOCK DIAGRAM OF THE SERIAL MICROPROCESSOR INTERFACE**

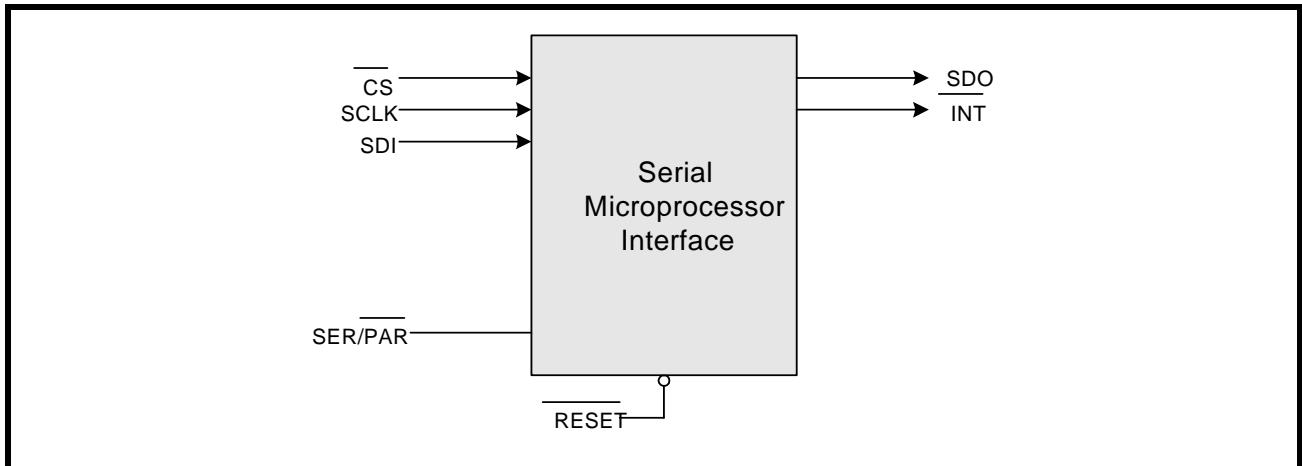

### 6.1.1   Serial Timing Information

The serial port requires 24 bits of data applied to the SDI (Serial Data Input) pin.  The Serial Microprocessor samples SDI on the rising edge of SCLK (Serial Clock Input).  The data is not latched into the device until all 24 bits of serial data have been sampled.  A timing diagram of the Serial Microprocessor is shown in Figure 36.

**FIGURE 36.  TIMING DIAGRAM FOR THE SERIAL MICROPROCESSOR INTERFACE**

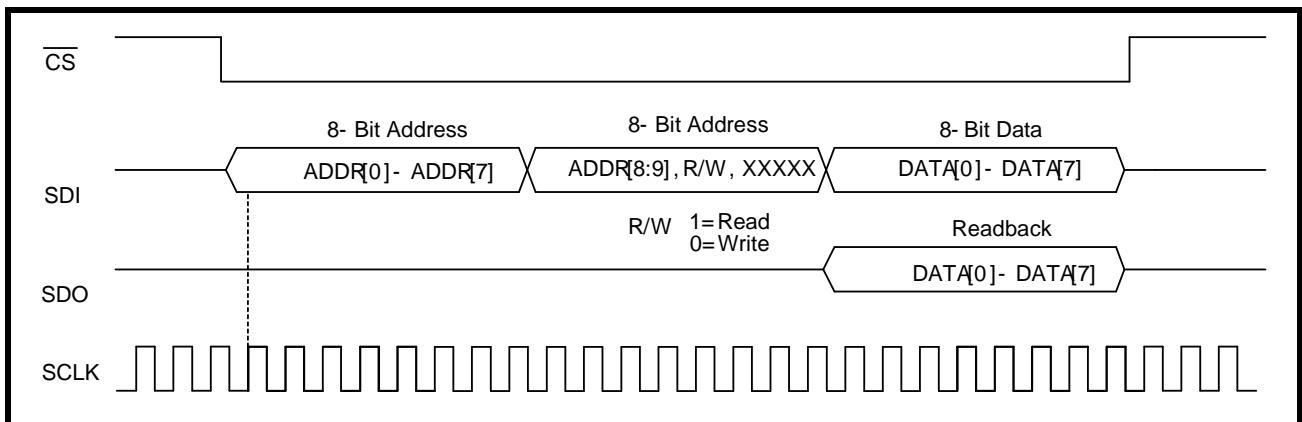

**NOTE:**  *For applications without a free running SCLK, a minimum of 1 SCLK pulse must be applied when $\overline{CS}$ is "High", befrore pulling $\overline{CS}$ "Low".*

### 6.1.2    24-Bit Serial Data Input Descritption

The serial data input is sampled on the rising edge of SCLK.  In readback mode, the serial data output is updated on the falling edge of SCLK.  The serial data must be applied to the LIU LSB first.  The 24 bits of serial data are described below.

### 6.1.3    ADDR[9:0] (SCLK1 - SCLK10)

The first 10 SCLK cycles are used to provide the address to which a Read or Write operation will occur. ADDR[0] (LSB) must be sent to the LIU first followed by ADDR[1] and so forth until all 10 address bits have been sampled by SCLK.

### 6.1.4    R/W (SCLK11)

The next serial bit applied to the LIU informs the microprocessor that a Read or Write operation is desired.  If the R/W bit is set to "0", the microprocessor is configured for a Write operation.  If the R/W bit is set to "1", the microprocessor is configured for a Read operation.

### 6.1.5    Dummy Bits (SCLK12 - SCLK16)

The next 5 SCLK cycles are used as dummy bits.  Five bits were chosen so that the serial interface can easily be divided into three 8-bit words to be compliant with standard serial interface devices.  The state of these bits are ignored and can hold either "0" or "1" during both Read and Write operations.

### 6.1.6    DATA[7:0] (SCLK17 - SCLK24)

The next 8 SCLK cycles are used to provide the data to be written into the internal register chosen by the address bits.  DATA[0] (LSB) must be sent to the LIU first followed by DATA[1] and so forth until all 8 data bits have been sampled by SCLK.  Once 24 SCLK cycles have been completed, the LIU holds the data until CS is pulled "High" whereby, the serial microprocessor latches the data into the selected internal register.

### 6.1.7    8-Bit Serial Data Output Description

The serial data output is updated on the falling edge of SCLK17 - SCLK24 if R/W is set to "1".  DATA[0] (LSB) is provided on SCLK17 to the SDO pin first followed by DATA[1] and so forth until all 8 data bits have been updated.  The SDO pin allows the user to read the contents stored in individual registers by providing the desired address on the SDI pin during the Read cycle.

**FIGURE 37. TIMING DIAGRAM FOR THE MICROPROCESSOR SERIAL INTERFACE**

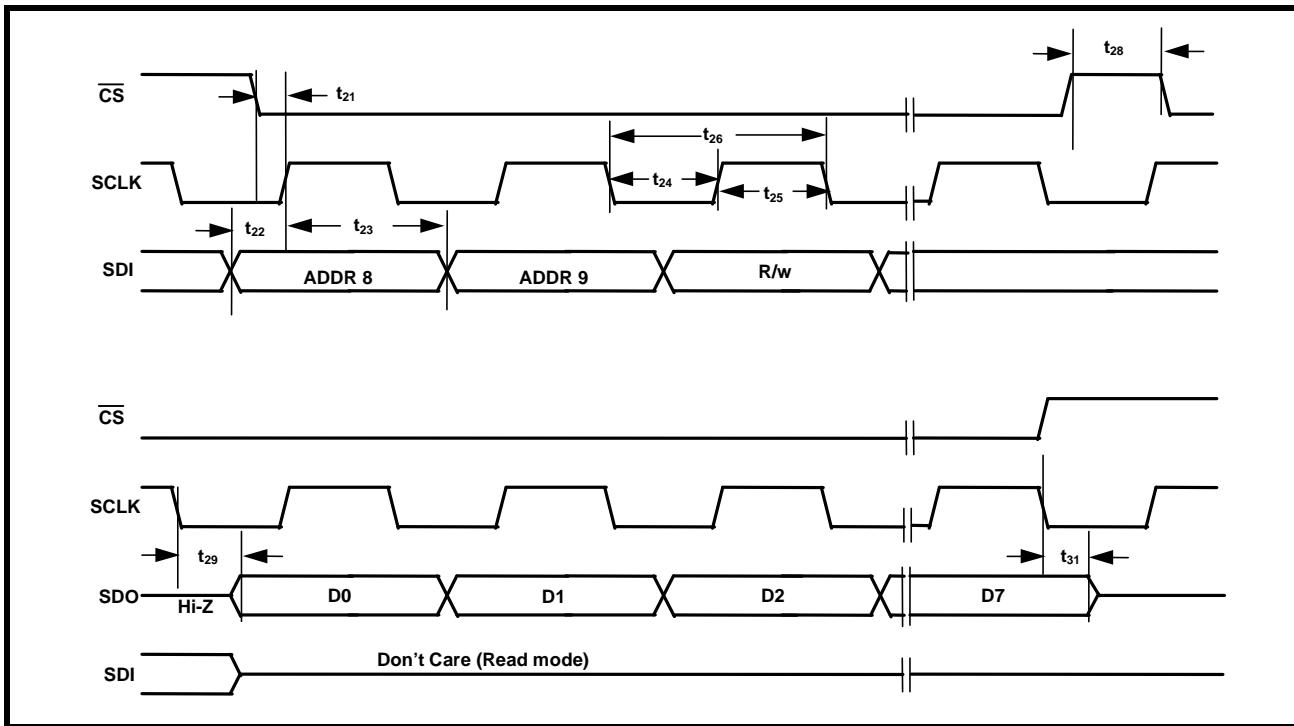

**TABLE 14: MICROPROCESSOR SERIAL INTERFACE TIMINGS ( $T_A = 25^0C$, $V_{DD}$=3.3V± 5% AND LOAD = 10PF)**

| SYMBOL | PARAMETER | MIN. | TYP. | MAX | UNITS |
|---|---|---|---|---|---|
| $t_{21}$ | $\overline{CS}$ Low to Rising Edge of SClk | 5 | | | ns |
| $t_{22}$ | SDI to Rising Edge of SClk | 5 | | | ns |
| $t_{23}$ | SDI to Rising Edge of SClk Hold Time | 5 | | | ns |
| $t_{24}$ | SClk "Low" Time | 20 | | | ns |
| $t_{25}$ | SClk "High" Time | 20 | | | ns |
| $t_{26}$ | SClk Period | 40 | | | ns |
| $t_{28}$ | $\overline{CS}$ Inactive Time | 40 | | | ns |
| $t_{29}$ | Falling Edge of SClk to SDO Valid Time | | | 5 | ns |
| $t_{31}$ | Rising edge of $\overline{CS}$ to High Z | | | 5 | ns |

### 6.2    Parallel Microprocessor Interface Block

The Parallel Microprocessor Interface section supports communication between the local microprocessor (µP) and the LIU.  The XRT83VSH316 supports an Intel asynchronous interface, Motorola 68K asynchronous, Power PC, and Motorola MPC8xx interface.  The microprocessor interface is selected by the state of the PTYPE[2:0] input pins.  Selecting the microprocessor interface is shown in Table 15.

**TABLE 15: SELECTING THE MICROPROCESSOR INTERFACE MODE**

| PTYPE[2:0] | MICROPROCESSOR MODE |
|:---:|:---:|
| 0h (000) | Intel 68HC11, 8051, 80C188 (Asynchronous) |
| 1h (001) | Motorola 68K (Asynchronous) |
| 5h (101) | Power PC (Synchronous) |
| 7h (111) | Motorola MPC8260, MPC860 (Synchronous) |

The XRT83VSH316 uses multipurpose pins to configure the device appropriately.  The local µP configures the LIU by writing data into specific addressable, on-chip Read/Write registers.  The microprocessor interface provides the signals which are required for a general purpose microprocessor to read or write data into these registers including two general purpose inputs/outputs (GPIO). The microprocessor interface also supports polled and interrupt driven environments.  A simplified block diagram of the microprocessor is shown in Figure 38.

**FIGURE 38.  SIMPLIFIED BLOCK DIAGRAM OF THE MICROPROCESSOR INTERFACE BLOCK**
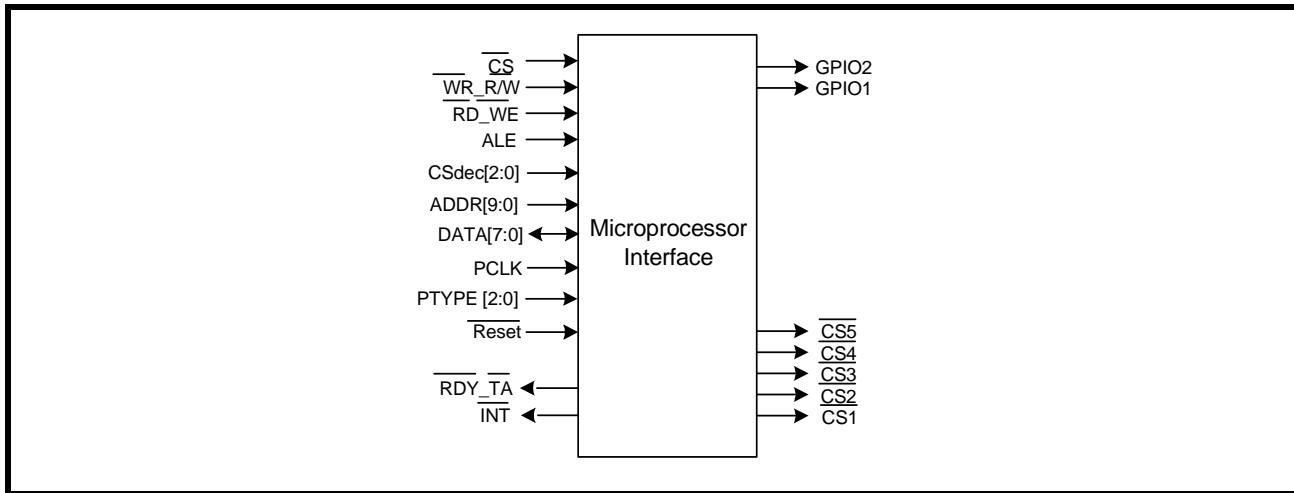

### 6.3　The Microprocessor Interface Block Signals

The LIU may be configured into different operating modes and have its performance monitored by software through a standard microprocessor using data, address and control signals.　These interface signals are described below in Table 16, Table 17, and Table 18. The microprocessor interface can be configured to operate in Intel mode or Motorola mode. When the microprocessor interface is operating in Intel mode, some of the control signals function in a manner required by the Intel 80xx family of microprocessors. Likewise, when the microprocessor interface is operating in Motorola mode, then these control signals function in a manner as required by the Motorola Power PC family of microprocessors.　(For using a Motorola 68K asynchronous processor, see Figure 42 and Table 22)　Table 16 lists and describes those microprocessor interface signals whose role is constant across the two modes. Table 17 describes the role of some of these signals when the microprocessor interface is operating in the Intel mode. Likewise, Table 18 describes the role of these signals when the microprocessor interface is operating in the Motorola Power PC mode.

**TABLE 16: XRT83VSH316 MICROPROCESSOR INTERFACE SIGNALS COMMON TO BOTH INTEL AND MOTOROLA MODES**

| PIN NAME | TYPE | DESCRIPTION |
|---|---|---|
| PTYPE[2:0] | I | **Microprocessor Interface Mode Select Input pins**<br>These three pins are used to specify the microprocessor interface mode.　The relationship between the state of these three input pins, and the corresponding microprocessor mode is presented in Table 15. |
| DATA[7:0] | I/O | **Bi-Directional Data Bus for register "Read" or "Write" Operations.** |
| CSdec[2:0] | I | **Chip Select Decoder Inputs**<br>The state of these 3 pins enable the Chip Selects for additional LIU devices.<br>**NOTE:** *See the 84-Channel Application Section of this datasheet.* |
| ADDR[9:0] | I | **Nine-Bit Address Bus Inputs**<br>The XRT83VSH316 LIU microprocessor interface uses a direct address bus. This address bus is provided to permit the user to select an on-chip register for Read/Write access. |
| $\overline{\text{CS}}$ | I | **Chip Select Input**<br>This active low signal selects the microprocessor interface of the XRT83VSH316 LIU and enables Read/Write operations with the on-chip register locations. |

**TABLE 17: INTEL MODE: MICROPROCESSOR INTERFACE SIGNALS**

| XRT83VSH316 PIN NAME | INTEL EQUIVALENT PIN | TYPE | DESCRIPTION |
|---|---|---|---|
| ALE_TS | ALE | I | **Address-Latch Enable:** This active high signal is used to latch the contents on the address bus ADDR[8:0]. The contents of the address bus are latched into the ADDR[8:0] inputs on the falling edge of ALE. |
| $\overline{\text{RD}}$_$\overline{\text{WE}}$ | $\overline{\text{RD}}$ | I | **Read Signal:** This active low input functions as the read signal from the local µP. When this pin is pulled "Low" (if $\overline{\text{CS}}$ is "Low") the LIU is informed that a read operation has been requested and begins the process of the read cycle. |
| $\overline{\text{WR}}$_R/$\overline{\text{W}}$ | $\overline{\text{WR}}$ | I | **Write Signal:** This active low input functions as the write signal from the local µP. When this pin is pulled "Low" (if $\overline{\text{CS}}$ is "Low") the LIU is informed that a write operation has been requested and begins the process of the write cycle. |
| $\overline{\text{RDY}}$_$\overline{\text{TA}}$ | $\overline{\text{RDY}}$ | O | **Ready Output:** This active low signal is provided by the LIU device.　It indicates that the current read or write cycle is complete, and the LIU is waiting for the next command. |

**TABLE 18: MOTOROLA MODE: MICROPROCESSOR INTERFACE SIGNALS**

| XRT83VSH316 PIN NAME | MOTOROLA EQUIVALENT PIN | TYPE | DESCRIPTION |
|---|---|---|---|
| ALE_TS | TS | I | **Transfer Start:** This active high signal is used to latch the contents on the address bus ADDR[8:0]. The contents of the address bus are latched into the ADDR[8:0] inputs on the falling edge of TS. |
| $\overline{WR}$_R/$\overline{W}$ | R/$\overline{W}$ | I | **Read/Write:** This input pin from the local µP is used to inform the LIU whether a Read or Write operation has been requested. When this pin is pulled "High", $\overline{WE}$ will initiate a read operation. When this pin is pulled "Low", $\overline{WE}$ will initiate a write operation. |
| $\overline{RD}$_$\overline{WE}$ | $\overline{WE}$ | I | **Write Enable:** This active low input functions as the read or write signal from the local µP dependent on the state of R/$\overline{W}$. When $\overline{WE}$ is pulled "Low" (If $\overline{CS}$ is "Low") the LIU begins the read or write operation. |
| No Pin | $\overline{OE}$ | I | **Output Enable:** This signal is not necessary for the XRT83VSH316 to interface to the MPC8260 or MPC860 Power PCs. |
| µPCLK | CLKOUT | I | **Synchronous Processor Clock:** This signal is used as the timing reference for the Power PC synchronous mode. |
| $\overline{RDY}$_$\overline{TA}$ | $\overline{TA}$ | O | **Transfer Acknowledge:** This active low signal is provided by the LIU device. It indicates that the current read or write cycle is complete, and the LIU is waiting for the next command. |

### 6.4    Intel Mode Programmed I/O Access (Asynchronous)

If the LIU is interfaced to an Intel type µP, then it should be configured to operate in the Intel mode. Intel type Read and Write operations are described below.

### Intel Mode Read Cycle

Whenever an Intel-type µP wishes to read the contents of a register, it should do the following.

1.  Place the address of the target register on the address bus input pins ADDR[9:0].
2.  While the µP is placing this address value on the address bus, the address decoding circuitry should assert the $\overline{CS}$ pin of the LIU, by toggling it "Low". This action enables further communication between the µP and the LIU microprocessor interface block.
3.  Toggle the ALE input pin "High". This step enables the address bus input drivers, within the microprocessor interface block of the LIU.
4.  The µP should then toggle the ALE pin "Low". This step causes the LIU to latch the contents of the address bus into its internal circuitry. At this point, the address of the register has now been selected.
5.  Next, the µP should indicate that this current bus cycle is a Read operation by toggling the $\overline{RD}$ input pin "Low". This action also enables the bi-directional data bus output drivers of the LIU.
6.  After the µP toggles the Read signal "Low", the LIU will toggle the $\overline{RDY}$ output pin "Low". The LIU does this in order to inform the µP that the data is available to be read by the µP, and that it is ready for the next command.
7.  After the µP detects the $\overline{RDY}$ signal and has read the data, it can terminate the Read Cycle by toggling the $\overline{RD}$ input pin "High".

**NOTE:** $\overline{ALE}$ can be tied "High" if this signal is not available.

### The Intel Mode Write Cycle

Whenever an Intel type µP wishes to write a byte or word of data into a register within the LIU, it should do the following.

1.  Place the address of the target register on the address bus input pins ADDR[9:0].
2.  While the µP is placing this address value on the address bus, the address decoding circuitry should assert the $\overline{CS}$ pin of the LIU, by toggling it "Low". This action enables further communication between the µP and the LIU microprocessor interface block.
3.  Toggle the ALE input pin "High". This step enables the address bus input drivers, within the microprocessor interface block of the LIU.
4.  The µP should then toggle the ALE pin "Low". This step causes the LIU to latch the contents of the address bus into its internal circuitry. At this point, the address of the register has now been selected.
5.  The µP should then place the byte or word that it intends to write into the target register, on the bi-directional data bus DATA[7:0].
6.  Next, the µP should indicate that this current bus cycle is a Write operation by toggling the $\overline{WR}$ input pin "Low". This action also enables the bi-directional data bus input drivers of the LIU.
7.  After the µP toggles the Write signal "Low", the LIU will toggle the $\overline{RDY}$ output pin "Low". The LIU does this in order to inform the µP that the data has been written into the internal register location, and that it is ready for the next command.

**NOTE:** $\overline{ALE}$ can be tied "High" if this signal is not available.

The Intel Read and Write timing diagram is shown in Figure 40.  The timing specifications are shown in Table 20.

**FIGURE 39. INTEL µP INTERFACE TIMING DURING PROGRAMMED I/O READ AND WRITE OPERATIONS WHEN ALE IS NOT TIED 'HIGH'**

| NA | $\overline{WR}$ Pulse Width ($t_4$) | 90 | - | ns |

### 6.5  MPC86X Mode Programmed I/O Access (Synchronous)

If the LIU is interfaced to a MPC86X type µP, it should be configured to operate in the MPC86X mode. MPC86X Read and Write operations are described below.

**MPC86X Mode Read Cycle**

1.  Place the address of the target register on the address bus input pins ADDR[9:0].
2.  While the µP is placing this address value on the address bus, the address decoding circuitry should assert the $\overline{CS}$ pin of the LIU, by toggling it "Low". This action enables further communication between the µP and the LIU microprocessor interface block.
3.  Next, the µP should indicate that this current bus cycle is a Read operation by pulling the R/$\overline{W}$ input pin "High".
4.  The LIU will toggle the $\overline{TA}$ output pin "Low". The LIU does this in order to inform the µP that the data is available to be read by the µP.
5.  After the µP detects the $\overline{TA}$ signal and has read the data, it can terminate the Read Cycle by toggling the $\overline{CS}$ input pin "High".

**MPC86X Mode Write Cycle**

1.  Place the address of the target register on the address bus input pins ADDR[9:0].
2.  While the µP is placing this address value on the address bus, the address decoding circuitry should assert the $\overline{CS}$ pin of the LIU, by toggling it "Low". This action enables further communication between the µP and the LIU microprocessor interface block.
3.  Next, the µP should indicate that this current bus cycle is a Write operation by pulling the R/$\overline{W}$ input pin "Low".
4.  Toggle the $\overline{WE}$ input pin "Low".
5.  After the µP toggles the $\overline{WE}$ signal "Low", the LIU will toggle the $\overline{TA}$ output pin "Low". The LIU does this in order to inform the µP that the data has been written into the internal register location.
6.  After the µP detects the $\overline{TA}$ signal, the Write operation is completed by toggling both $\overline{WE}$ and $\overline{CS}$ pins "High".

The Motorola Read and Write timing diagram is shown in Figure 41.  The timing specifications are shown in Table 21.

### 7.0   REGISTER DESCRIPTIONS

To use any of the diagnostic features for the Line or System interface, the LIU must be placed in Single Rail mode. The following table is intended to be used as a simplified register map which summarizes the address locations of the LIU features.

**TABLE 23: MICROPROCESSOR REGISTER ADDRESS (ADDR[8:0])**

| REGISTER NUMBER | ADDRESS (HEX) | FUNCTION |
|---|---|---|
| 1 - 16 | 0x000 - 0x00F | Global Configuration Registers |
| 17 - 36 | 0x020 - 0x033 | Channel 0 Registers |
| 37 - 56 | 0x040 - 0x053 | Channel 1 Registers |
| 57 - 76 | 0x060 - 0x073 | Channel 2 Registers |
| 77 - 96 | 0x080 - 0x093 | Channel 3 Registers |
| 97 - 116 | 0x0A0 - 0x0B3 | Channel 4 Registers |
| 117 - 136 | 0x0C0 - 0x0D3 | Channel 5 Registers |
| 137 - 156 | 0x0E0 - 0x0F3 | Channel 6 Registers |
| 157 - 176 | 0x100 - 0x113 | Channel 7 Registers |
| 177 - 196 | 0x120 - 0x133 | Channel 8 Registers |
| 197 - 216 | 0x140 - 0x153 | Channel 9 Registers |
| 217 - 236 | 0x160 - 0x173 | Channel 10 Registers |

### 7.3      Offset for Programming the Channel Number, N

The offset for programming the channel number can be added to the register value for determining the actual address. Address = Offset + Register Value. The offset is the following: Channel 0 = 0x020, Channel 1 = 0x040, Channel 2 = 0x060, Channel 3 = 0x080, Channel 4 = 0x0A0, Channel 5 = 0x0C0, Channel 6 = 0x0E0, Channel 7 = 0x100, Channel 8 = 0x120, Channel 9 = 0x140, Channel 10 = 0x160, Channel 11 = 0x180, Channel 12 = 0x1A0, Channel 13 = 0x1C0, Channel 14 = 0x1E0, and Channel 15 = 0x200.

***Example: Channel 10, Register 0xN13 in*** Table 25***, 0x160 + 0xN13 = 0x173. See*** Table 23 ***for more details.***

### CLOCK SELECT REGISTER

The input clock source is used to generate all the necessary clock references internally to the LIU. The microprocessor timing is derived from a PLL output which is chosen by programming the Clock Select Bits in register 0x0009h. Therefore, if the clock selection bits are being programmed, the frequency of the PLL output will be adjusted accordingly. During this adjustment, it is important to "Not" write to any other bit location within the same register while selecting the input/output clock frequency. For best results, register 0x0009h can be broken down into two sub-registers with the MSB being bit D4 and the LSB being bits D[3:0] as shown in Figure 43.

**NOTE:** *Bits D[7:5] are reserved.*

**FIGURE 43. REGISTER 0X0009H SUB REGISTERS**

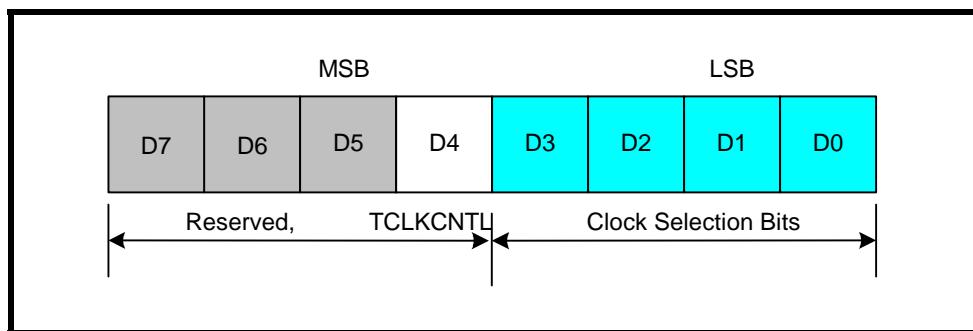

Programming Examples:

**Example 1**: Changing bits D[7:4]

If bit D4 is the only values within the register that will change in a WRITE process, the microprocessor only needs to initiate ONE write operation.

**Example 2**: Changing bits D[3:0]

If bits D[3:0] are the only values within the register that will change in a WRITE process, the microprocessor only needs to initiate ONE write operation.

**Example 3**: Changing bits within the MSB and LSB

In this scenario, one must initiate TWO write operations such that the MSB and LSB do not change within ONE write cycle. It is recommended that the MSB and LSB be treated as two independent sub-registers. One can either change the clock selection bits D[3:0] (LSB) and then change bit D4 (MSB) on the SECOND write, or vice-versa. No order or sequence is necessary.
