NOTES

¹The A_{IN} pin presents a very high impedance dynamic load which varies with clock frequency.

²Temperature ranges are as follows: A, B Versions; -40°C to +85°C; S, T Versions; -55°C to +125°C.

³Apply after calibration at the temperature of interest. Full-scale error applies for both unipolar and bipolar input ranges.

⁴Total drift over the specified temperature range since calibration at power-up at +25°C. This is guaranteed by design and/or characterization. Recalibration at any temperature will remove these errors.

⁵In unipolar mode the offset can have a negative value ($-V_{REF}$) such that the unipolar mode can mimic bipolar mode operation.

⁶The specifications for input overrange and for input span apply additional constraints on the offset calibration range.

⁷For unipolar mode, input span is the difference between full-scale and zero scale. For bipolar mode, input span is the difference between positive and negative full-scale points. When using less than the maximum input span, the span range may be placed anywhere within the range of $\pm(V_{REF} + 0.1)$.

⁸All digital outputs unloaded. All digital inputs at 5 V CMOS levels.

⁹Applies in 0.1 Hz to 10 Hz bandwidth. PSRR at 60 Hz will exceed 120 dB due to the digital filter.

¹⁰CLKIN is stopped. All digital inputs are grounded.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS¹

Derates above +75°C by 10 mW/°C

CAUTION

ESD (electrostatic discharge) sensitive device. The digital control inputs are diode protected; however, permanent damage may occur on unconnected devices subject to high energy electrostatic fields. Unused devices must be stored in conductive foam or shunts. The protective foam should be discharged to the destination socket before devices are removed.

PIN FUNCTION DESCRIPTION

Pin	Mnemonic	Description
1	MODE	Selects the Serial Interface Mode. If MODE is tied to -5 V , the AD7701 will operate in the asynchronous communications (AC) mode. The SCLK pin is configured as an input, and data is transmitted in two bytes, each with one start bit and two stop bits. If MODE is tied to DGND, the synchronous external clocking (SEC) mode is selected. SCLK is configured as an input, and the output appears without formatting, the MSB coming first. If MODE is tied to $+5\text{ V}$, the AD7701 operates in the synchronous self-clocking (SSC) mode. SCLK is configured as an output, with a clock frequency of $f_{\text{CLKIN}}/4$ and 25% duty-cycle.
2	CLKOUT	Clock Output to generate an Internal Master Clock by connecting a crystal between CLKOUT and CLKIN. If an external clock is used, CLKOUT is not connected.
3	CLKIN	Clock Input for External Clock.
4, 17	SC1, SC2	System Calibration Pins. The state of these pins, when CAL is taken high, determines the type of calibration performed.
5	DGND	Digital Ground. Ground reference for all digital signals.
6	DV _{SS}	Digital Negative Supply, -5 V nominal.
7	AV _{SS}	Analog Negative Supply, -5 V nominal.
8	AGND	Analog Ground. Ground reference for all analog signals.
9	A _{IN}	Analog Input.
10	V _{REF}	Voltage Reference Input, $+2.5\text{ V}$ nominal. This determines the value of positive full-scale in the unipolar mode and of both positive and negative full-scale in the bipolar mode.
11	SLEEP	Sleep mode pin. When this pin is taken low, the AD7701 goes into a low-power mode with typically $10\text{ }\mu\text{W}$ power consumption.
12	BP/ $\overline{\text{UP}}$	Bipolar/Unipolar Mode Pin. When this pin is low, the AD7701 is configured for a unipolar input range going from AGND to V _{REF} . When Pin 12 is high, the AD7701 is configured for a bipolar input range, $\pm V_{\text{REF}}$.
13	CAL	Calibration Mode Pin. When CAL is taken high for more than 4 cycles, the AD7701 is reset and performs a calibration cycle when CAL is brought low again. The CAL pin can also be used as a strobe to synchronize the operation of several AD7701s.
14	AV _{DD}	Analog Positive Supply, $+5\text{ V}$ nominal.
15	DV _{DD}	Digital Positive Supply, $+5\text{ V}$ nominal.
16	$\overline{\text{CS}}$	Chip Select Input. When $\overline{\text{CS}}$ is brought low, the AD7701 will begin to transmit serial data in a format determined by the state of the MODE pin.
18	$\overline{\text{DRDY}}$	Data Ready output. $\overline{\text{DRDY}}$ is low when valid data is available in the output register. It goes high after transmission of a word is completed. It also goes high for four clock cycles when a new data word is being loaded into the output register, to indicate that valid data is not available, irrespective of whether data transmission is complete or not.
19	SCLK	Serial Clock Input/Output. The SCLK pin is configured as an input or output, dependent on the type of serial data transmission that has been selected by the MODE pin. When configured as an output in the synchronous self-clocking mode, it has a frequency of $f_{\text{CLKIN}}/4$ and a duty cycle of 25%.
20	SDATA	Serial Data Output. The AD7701's output data is available at this pin as a 16-bit serial word. The transmission format is determined by the state of the MODE pin.

PIN CONFIGURATION

t_{19}	200	200	ns max	SCLK Falling Edge to Hi-Z Delay. Typically 100 ns

NOTES

¹Sample tested at +25°C to ensure compliance. All input signals are specified with $t_r = t_f = 5\text{ ns}$ (10% to 90% of 5 V) and timed from a voltage level of 1.6 V.

²See Figures 1 to 5.

³CLKIN Duty Cycle range is 20% to 80%. CLKIN must be supplied whenever the AD7701 is not in SLEEP mode. If no clock is present in this case, the device can draw higher current than specified and possibly become uncalibrated.

⁴The AD7701 is production tested with f_{CLKIN} at 4.096 MHz. It is guaranteed by characterization to operate at 200 kHz.

⁵Specified using 10% and 90% points on waveform of interest.

⁶In order to synchronize several AD7701s together using the SLEEP pin, this specification is met.

⁷ t_4 and t_{13} are measured with the load circuit of Figure 1 and defined as the time required for an output to cross 0.8 V or 2.4 V.

⁸ t_8 , t_{10} , t_{15} and t_{16} are derived from the measured time taken by the data outputs to change 0.5 V when loaded with the circuit of Figure 1. The measured number is then extrapolated back to remove the effects of charging or discharging the 100 pF capacitor. This means that the time quoted in the Timing Characteristics is the true bus relinquish time of the part and as such as independent of external bus loading capacitance.

⁹If $\overline{CS}$ is returned high before all 16 bits are output, the SDATA and SCLK outputs will complete the current data bit and then go to high impedance.

¹⁰If $\overline{CS}$ is activated asynchronously to $\overline{DRDY}$, $\overline{CS}$ will not be recognized if it occurs when $\overline{DRDY}$ is high for four clock cycles. The propagation delay time may be as great as 4 CLKIN cycles plus 160 ns. To guarantee proper clocking of SDATA when using asynchronous $\overline{CS}$, the SCLK input should not be taken high sooner than 4 CLKIN cycles plus 160 ns after $\overline{CS}$ goes low.

¹¹SDATA is clocked out on the falling edge of the SCLK input.

TERMINOLOGY

LINEARITY ERROR

This is the maximum deviation of any code from a straight line passing through the endpoints of the transfer function. The endpoints of the transfer function are Zero-Scale (not to be confused with Bipolar Zero), a point 0.5 LSB below the first code transition (000 . . . 000 to 000 . . . 001) and Full-Scale, a point 1.5 LSB above the last code transition (111 . . . 110 to 111 . . . 111). The error is expressed as a percentage of full scale.

DIFFERENTIAL LINEARITY ERROR

This is the difference between any code's actual width and the ideal (1 LSB) width. Differential Linearity Error is expressed in LSBs. A differential linearity specification of ± 1 LSB or less guarantees monotonicity.

POSITIVE FULL-SCALE ERROR

Positive Full-Scale Error is the deviation of the last code transition (111 . . . 110 to 111 . . . 111) from the ideal ($V_{REF} - 3/2$ LSBs). It applies to both positive and negative analog input ranges and it is expressed in microvolts.

UNIPOLAR OFFSET ERROR

Unipolar Offset Error is the deviation of the first code transition from the ideal (AGND + 0.5 LSB) when operating in the unipolar mode. It is expressed in microvolts.

BIPOLAR ZERO ERROR

This is the deviation of the mid-scale transition (0111 . . . 111 to 1000 . . . 000) from the ideal (AGND - 0.5 LSB) when operating in the bipolar mode. It is expressed in microvolts.

BIPOLAR NEGATIVE FULL-SCALE ERROR

This is the deviation of the first code transition from the ideal ($-V_{REF} + 0.5$ LSB), when operating in the bipolar mode. It is expressed in microvolts.

POSITIVE FULL-SCALE OVERRANGE

Positive Full-Scale Overrange is the amount of overhead available to handle input voltages greater than $+V_{REF}$ (for example, noise peaks or excess voltages due to system gain errors in system calibration routines) without introducing errors due to overloading the analog modulator or overflowing the digital filter. It is expressed in millivolts.

NEGATIVE FULL-SCALE OVERRANGE

This is the amount of overhead available to handle voltages below $-V_{REF}$ without overloading the analog modulator or overflowing the digital filter. Note that the analog input will accept negative voltage peaks even in the unipolar mode. The overhead is expressed in millivolts.
