¹FEATURES DESCRIPTION

 Bipolar Output: Up to ±16V The DAC7716 is ^a high-accuracy, quad-channel, **Unipolar Output: 0V to +20V** 12-bit digital-to-analog converter (DAC) that operates from supply voltages of $±5V$ to $±18V$ in bipolar output mode, and from ±5V to +24V/–12V in unipolar mode. **Relative Accuracy: ¹ LSB Max** With ^a 5V reference, the DAC7716 can be configured **Low Zero and Gain Errors** to output $\pm 10V$, $\pm 5V$, 0V to 20V, or 0V to 10V. The DAC7716 provides 12-bit monotonicity, excellent integral nonlinearity (INL) error of $±1$ LSB, low glitch, and low noise over the operating temperature range of –40°C to +105°C. This device is trimmed in **Error**
 Error Exercise: 60nV/ \sqrt{Hz} **and production** for very low zero and gain errors. In

addition, the DAC7716 implements a **Low Noise: 60nV/√Hz** addition, the DAC7716 implements a user-programmable system-level calibration function to achieve ±0.0078 LSB zero error and ±0.0625 LSB gain error.

The DAC7716 has integrated reference buffers and **Power-Down Mode Power-Down Mode output** buffers. It features a standard high-speed **SPI™: Up to 50MHz, 1.8V/3V/5V Logic** 1.8V, 3V, or 5V serial peripheral interface (SPI) that operates at clock rates of up to 50MHz to communicate with ^a DSP or microprocessor. The four **Operating Temperature: –40°C to +105°C**
 DAC channels and the auxiliary registers are
 Packages: QFN-40 (6x6mm). TQFP-48 (7x7mm) addressed with four address bits. The device features double-buffered interface logic for simultaneous updates of all DACs. An asynchronous load input (LDAC) transfers data from the input data register to the DAC latch, and the contents of the DAC latch set the output voltage. The asynchronous RST input sets the output of all four DACs to 0V. The V_{MON} pin is an **Communications Communications analog monitor output that multiplexes the individual** DAC outputs or the AIN pin.

> The DAC7716 is pin-compatible with the [DAC8734](http://focus.ti.com/docs/prod/folders/print/dac8734.html) (16-bit) and the [DAC8234](http://focus.ti.com/docs/prod/folders/print/dac8234.html) (14-bit).

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

SBAS463A–AUGUST 2009–REVISED SEPTEMBER 2009 ... **www.ti.com**

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

PACKAGE/ORDERING INFORMATION(1)

(1) For the most current package and ordering information, see the Package Option Addendum at the end of this data sheet, or see the TI website at www.ti.com.

ABSOLUTE MAXIMUM RATINGS(1)

Over operating free-air temperature range (unless otherwise noted).

(1) Stresses above those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. Exposure to absolute maximum conditions for extended periods may affect device reliability.

(2) AV_{SS} must be < -3.5V if AV_{DD} \geq 1V.

(3) T_A is the ambient temperature.

www.ti.com... SBAS463A–AUGUST 2009–REVISED SEPTEMBER 2009

ELECTRICAL CHARACTERISTICS

All specifications at T_A = T_{MIN} to T_{MAX}, AV_{DD} = +11V to +18V, AV_{SS} = –11V to –18V, V_{REF} = REF-A = REF-B = +5V, DV $_{\text{DD}}$ = +5V, IOV $_{\text{DD}}$ = +1.8V to DV $_{\text{DD}}$, AGND = DGND = REFGND-A = REFGND-B = SGND-x = 0V, and DAC gain = 4, unless otherwise noted.

(1) See the *User Calibration for [Zero-Code](#page-18-0) Error and Gain Error* section for details.

(2) Specified by design and characterization.
(3) DC crosstalk is the dc change in the outp DC crosstalk is the dc change in the output of one channel as a result of a full-scale code change and subsequent output change on another channel. The DAC outputs are buffered by op amps that share common AV_{DD} and AV_{SS} power supplies. Multiple V_{DD} and V_{SS} terminals are provided to minimize dc crosstalk.

(4) The analog output must not be greater than $(AV_{DD} - 1.0V)$ and must not be less than $(AV_{SS} + 1.0V)$.

(5) When the output current is greater than the specification, the current is clamped at the specified maximum value.

All specifications at T_A = T_{MIN} to T_{MAX}, AV_{DD} = +11V to +18V, AV_{SS} = –11V to –18V, V_{REF} = REF-A = REF-B = +5V, DV $_{\text{DD}}$ = +5V, IOV $_{\text{DD}}$ = +1.8V to DV $_{\text{DD}}$, AGND = DGND = REFGND-A = REFGND-B = SGND-x = 0V, and DAC gain = 4, unless otherwise noted.

(6) Specified by design and characterization.

(7) Slew rate is measured from 10% to 90% of the transition when the output changes from negative full-scale to positive full-scale.

(8) *Digital-to-analog glitch* is defined as the amount of energy injected into the analog output at the major code transition. It is specified as the area of the glitch in nV-s. It is measured by toggling the DAC register data between 000h and FFFh in twos complement format. (9) *Channel-to-channel isolation* refers to the ratio of the signal amplitude at the output of one DAC channel to the amplitude of the

sinusoidal signal on the reference input of another DAC channel. It is expressed in dB and measured at midscale. (10) *DAC-to-DAC crosstalk* is the glitch impulse that appears at the output of one DAC as ^a result of both the full-scale digital code and

subsequent analog output change at another DAC. It is measured with LDAC tied low and expressed in nV-s. (11) *Digital crosstalk* is the glitch impulse transferred to the output of one converter as ^a result of ^a full-scale code change in the DAC input

register of another converter. It is measured when the DAC output is not updated, and is expressed in nV-s. (12) *Digital feedthrough* is the glitch impulse injected to the output of ^a DAC as ^a result of ^a digital code change in the DAC input register of the same DAC. It is measured with the full-scale digital code change without updating the DAC output, and is expressed in nV-s.

www.ti.com... SBAS463A–AUGUST 2009–REVISED SEPTEMBER 2009

ELECTRICAL CHARACTERISTICS (continued)

All specifications at T_A = T_{MIN} to T_{MAX}, AV_{DD} = +11V to +18V, AV_{SS} = –11V to –18V, V_{REF} = REF-A = REF-B = +5V, DV $_{\text{DD}}$ = +5V, IOV $_{\text{DD}}$ = +1.8V to DV $_{\text{DD}}$, AGND = DGND = REFGND-A = REFGND-B = SGND-x = 0V, and DAC gain = 4, unless otherwise noted.

(13) Specified by design and characterization.

(14) AV_{DD} should not be greater than +24V or less than +4.75V. Also, AV_{DD} should not be less than (2 × V_{REF} + 1V) for bipolar output mode and should not be less than (Gain × V_{REF} + 1V) for unipolar output mode. In any case, (AV_{DD} – AV_{SS}) ≤ +36V.

(15) AV_{SS} should not be greater than –4.75V or less than –18V. Also, AV_{SS} should not be greater than (–2 × V_{REF} – 1V). In any case, (AV_{DD} $-$ AV_{SS}) ≤ +36V.

UNIPOLAR GAIN ERROR PRODUCTION DISTRIBUTION UNIPOLAR ZERO ERROR PRODUCTION DISTRIBUTION

THEORY OF OPERATION

DAC ARCHITECTURE

The DAC7716 is ^a highly-integrated, quad-channel, 12-bit, voltage-output DAC with internal reference buffers and output buffers. Each channel consists of an R-2R ladder configuration with the three MSBs segmented, followed by an operational amplifier, as shown in Figure 41. The DAC7716 has a high-impedance, buffered reference input; the output of the reference buffers drives the R-2R ladders. The output buffer is designed to allow user-configurable adjustments, giving the DAC7716 four different output voltage range settings. With the production trim process, this device has excellent dc accuracy and ac performance.

Figure 41. DAC7716 Architecture

CHANNEL GROUPS

The four DAC channels are arranged into two groups (A and B) with two channels per group. Group A consists of DAC-0 and DAC-1, and Group B consists of DAC-2 and DAC-3. The two DAC channels of Group A derive their reference voltage from REF-A, and those of Group B from REF-B.

USER-CALIBRATION FOR ZERO ERROR AND GAIN ERROR

The DAC7716 implements ^a user-calibration function that allows for trimming the system gain and zero errors. Each DAC channel has ^a Gain Register and Zero Register and the DAC output is calibrated according to the value of the corresponding registers. The range of gain adjustment is typically ±0.195% of full-scale with 0.0625 LSB per step. The zero code adjustment is typically ±0.0488% of full-scale with 0.0078 LSB per step. The input data format of the Gain and Zero registers is twos complement. Refer to [Table](#page-27-0) 9 and [Table](#page-27-0) 10 for more details.

If the system-level calibration is not needed, these registers should be left at the respective default values (0000h) at power-on.

[DAC7716](http://focus.ti.com/docs/prod/folders/print/dac7716.html)

SBAS463A–AUGUST 2009–REVISED SEPTEMBER 2009 ... **www.ti.com**

TRANSFER FUNCTION FOR THE ANALOG OUTPUTS (VOUT-0 to VOUT-3)

For bipolar output:

$$
V_{OUT} = Gain \times V_{REF} \times \left(\frac{INV_CODE}{4096} + \frac{ZERO_CODE}{128 \times 4096}\right) \times \left(1 + \frac{GAIN_CODE}{32 \times 4096}\right)
$$
\n(1)

For unipolar output:

$$
V_{OUT} = Gain \times V_{REF} \times \left(\frac{INV_CODE}{4096} + \frac{ZERO_CODE}{128 \times 4096}\right) \times \left(1 + \frac{GAIN_CODE}{16 \times 4096}\right)
$$
\n(2)

Where:

GAIN is the DAC gain, which can be set to x2 or x4 and is determined by the connection of pins R_{FBT} -x and

 R_{FB2} -x to V_{OUT} -x, and the GAIN bit in the Command Register.

INPUT_CODE is the decimal equivalent value of the code written into the DAC input register.

ZERO_CODE is the decimal equivalent value of the code written into the Zero Register.

GAIN_CODE is the decimal equivalent value of the code written into the Gain Register.

Note that the output voltage must not be greater than $(AV_{DD} - 1.0V)$ or less than $(AV_{SS} + 1.0V)$; otherwise, the output may be saturated.

Input Data Format

For bipolar output operation, INPUT_CODE is always twos complement, and can accept values between –2048 to 2047.

For unipolar output operation, INPUT_CODE is always straight binary, and can accept values between 0 to 4095.

GAIN CODE is always in twos complement format, and can accept values between –128 and +127.

ZERO_CODE is always in twos complement format and can accept values between –256 and +255.

The data written to the Command and Monitor registers are written as specified in the definitions. For read operations, the read-back data format is the same as the format used to write to the device. Refer to the *[Internal](#page-25-0) [Registers](#page-25-0)* section for more details.

OUTPUT RANGE

Each channel of the DAC7716 implements an output amplifier that provides ^a unipolar output or ^a bipolar output with a gain of 2 or 4. The output span equals the gain times the reference voltage. For a 5V reference, the output range can be configured as ±10V, ±5V, 0V to 20V, or 0V to 10V. The status of the UNI/BIP pin determines the output mode (unipolar or bipolar) of each group. When the UNI/BIP-A pin is high, the outputs of Group A (DAC-0 and DAC-1) are unipolar; when the pin is low, the outputs of Group A are bipolar. Similarly, the UNI/BIP-B pin defines the output mode of Group B (DAC-2 and DAC-3).

Each individual DAC can be configured with a gain of 4 or a gain of 2. To set the gain = 4, connect R_{FB1} -x to V_{OUT} -x with R_{FB2}-x left open, and set the gain bit for that channel to '1' in the Command Register. To set the gain = 2, connect both R_{FB1}-x and R_{FB2}-x to V_{OUT}-x, and set the gain bit for that channel to '0'. The gain bits in the Command Register are set to '1' by default at power-on or reset, and must be cleared to '0' for gain ⁼ 2.

Note that the power supplies must meet the following requirements:

- • AV_{DD} must not be greater than 24V or less than 4.75V, and AV_{SS} must not be greater than $-4.75V$ or less than –18V. In any case, $(AV_{DD} - AV_{SS}) \leq 36V$.
- •For bipolar mode: $AV_{DD} \ge 2 \times V_{REF} + 1V$, and $AV_{SS} \le -2 \times V_{REF} - 1V$.
- •For unipolar mode: $AV_{DD} \geq Gain \times V_{REF} + 1V$, and $AV_{SS} \leq -2 \times V_{REF} - 1V$.

For example, for a 5V reference in bipolar operation, the minimum supplies must be at least ±11V, regardless of whether the output range is ±5V or ±10V. For unipolar operation with the same reference, the supplies must be at least ±11V for ^a 0V to 10V operation, and +21V/–11V for ^a 0V to +20V operation.

UPDATING THE DAC OUTPUTS

The DAC7716 has ^a double-buffered interface that consists of two register banks for every channel: the input register and the DAC latch. The digital code is transferred from the SPI shift register to the addressed channel input register upon completion of ^a valid write sequence. The DAC latch contains the digital code used by the resistor R-2R ladder. The contents of the DAC latch define the output from the DAC. The DAC outputs can be updated individually or simultaneously. The DAC7716 updates the DAC latch only if it has been accessed since the last time the LDAC pin was brought low or the LD bit in the Command Register was set to '1', thereby eliminating any unnecessary glitch. The DAC channels that were not accessed are not reloaded, and the output values remain unchanged.

Individual DAC Channel Update

In this mode, the LDAC pin is held low while the CS pin is low and the data are clocked into the SPI shift register. At the end of the data transfer into the shift register, the \overline{CS} pin is brought high. This action updates both the addressed input data register and the corresponding DAC latch register. The DAC latch register controls the R-2R switches; thus, an update on the DAC latch register updates the corresponding DAC channel analog output.

Simultaneous Update of Multiple DAC Channels

In this mode, the \overline{LDAC} pin is held high while the \overline{CS} pin is low and data are clocked into the SPI shift register. At the end of the data transfer into the shift register, the $\overline{\text{CS}}$ pin is brought high. This action updates only the addressed input data register; it does not update the DAC latch register or change the output. The DAC latch and the analog output are updated only when the LDAC pin goes low, or when the LD bit in the Command Register is set to '1' at anytime after the input data register is written.

HARDWARE RESET

When the RST pin is low, the device is in hardware reset. All the analog outputs (V_{OUT} -0 to V_{OUT} -3), the input registers, and the DAC latches are set to the reset values shown in Table 1. All registers are loaded with default values. Communication is disabled, and the signals on the SDI, \overline{CS} , and SCLK pins are ignored. On the rising edge of the RST pin, the analog outputs (V_{OUT} -0 to V_{OUT} -3) maintain the reset value (0V) until a new value is programmed. After the RST pin goes high, the device returns to normal operation. Note that the default values of the gain bits in the Command Register are '1' after ^a reset. For gain ⁼ 2, the gain bits must be cleared to '0'.

Table 1. Reset Values

Setting the RST bit in the Command Register to '1' performs ^a software reset, which is functionally the same as ^a hardware reset. After reset completes, the RST bit returns to '0' automatically.

POWER-ON RESET

On power-on, the input data registers and DAC latches are loaded with the value defined by the UNI/BIP pins (see Table 1). All other registers are loaded with default values. After power-on, the outputs of the V_{OUT} pins are set to 0V.

SBAS463A–AUGUST 2009–REVISED SEPTEMBER 2009 ... **www.ti.com**

ANALOG OUTPUT MONITOR PIN (VMON)

The V_{MON} pin is the analog output monitor. The analog output monitor function consists of an analog multiplexer addressed via the serial interface, allowing one of the four channel outputs or the AIN input to be routed to this pin for monitoring. The monitor function is controlled by the Monitor Register, which allows the monitored output to be enabled or disabled. When all multiplexer channels are disabled, the monitor output is high impedance; therefore, several monitor outputs can be connected in parallel with only one enabled at ^a time. [Table](#page-26-0) 5 shows the settings relevant to the monitor function.

Note that the multiplexer is implemented as ^a series of analog switches. Care should be taken to ensure the maximum current from the V_{MON} pin must not be greater than the given specification because such a condition could conceivably cause a large amount of current to flow from the input of the multiplexer (that is, from V_{OUT} -x or AIN) to the output of the multiplexer (V_{MON}). Also, the V_{MON} pin output impedance is approximately 2.2kΩ; therefore, V_{MON} should be measured with a high-impedance input.

POWER-DOWN MODE

The DAC7716 implements ^a group power-down feature to reduce power consumption in case some channels are idle. When the power-down bit (PD-A and/or PD-B) in the Command Register is set to '1', the corresponding group goes into ^a power-down state. During power-down, the reference buffer and output buffers of that group are powered down and the corresponding analog outputs are set to 0V through an internal 10kΩ resistor to AGND. The contents of the internal registers do not change, and the bus interface remains active in order to continue communication and receive commands from the host controller. Any internal register can be read from or written to. The host controller can wake the device from power-down mode and return to normal operating mode by clearing the power-down bit (PD-A and/or PD-B) in the Command Register. Recovery completes in approximately 50µs.

POWER-SUPPLY SEQUENCING

In order to ensure proper initialization of the DAC7716, the digital supplies (DV_{DD} and IOV_{DD}) and logic inputs (UNI/BIP-x) must be applied before AV_{SS} and AV_{DD}. Additionally, AV_{SS} must be applied before AV_{DD} unless both can ramp up at the same time. REF-x should be applied after AV_{DD} comes up in order to make sure the ESD protection circuitry does not turn on.

GENERAL-PURPOSE INPUT/OUTPUT PINS (GPIO-0, -1)

The GPIO-0 and GPIO-1 pins are general-purpose, bidirectional, digital input/output (I/O) signals, as Figure 42 shows. These pins can receive an input or produce an output. When the GPIO-n pin acts as an output, it has an open-drain, and the status is determined by the corresponding GPIO-n bit of the Command Register. The output status is high impedance when the GPIO-n bit is set to '1', and is logic low when the GPIO-n bit is cleared ('0'). Note that ^a 10kΩ pullup resistor is required when using the GPIO-n pin as an output.

To use the GPIO-n pin as an input, the GPIO-n bits in the Command Register must be set to '1'. When the GPIO-n pin acts as input, the digital value on the pin is acquired by reading the GPIO-n bit.

After ^a power-on reset or any forced hardware or software reset, all GPIO-n bits are set to '1', and the GPIO-n pin goes to ^a high-impedance state.

Figure 42. GPIO Pins

[DAC7716](http://focus.ti.com/docs/prod/folders/print/dac7716.html)

www.ti.com... SBAS463A–AUGUST 2009–REVISED SEPTEMBER 2009

SERIAL INTERFACE

The DAC7716 is controlled over ^a versatile, three-wire serial interface that operates at clock rates of up to 50MHz and is compatible with SPI, QSPI™, Microwire™, and DSP™ standards.

SPI Shift Register

The SPI Shift Register is 24 bits wide. Data are loaded into the device MSB first as a 24-bit word under the control of the serial clock input, SCLK. The falling edge of CS starts the communication cycle. Data are latched into the SPI Shift Register on the falling edge of SCLK while CS is low. When CS is high, SCLK is blocked, SDI is ignored, and the SDO line is in ^a high-impedance state. The contents of the SPI Shift Register are loaded into the addressed internal register on the rising edge of CS. The SPI Shift Register consists of ^a read/write bit, four register address bits, 12 data bits, and seven reserved bits, as shown in [Table](#page-24-0) 2. The timing for this operation is shown in the *Timing [Diagrams](#page-8-0)* section. When the device is loaded, the command is decoded, and the new data are transferred into the proper data registers.

The serial interface works with both continuous and non-continuous serial clocks. A continuous SCLK source can only be used if \overline{CS} is held low for the correct number of clock cycles. In gated clock mode, a burst clock containing the exact number of clock cycles must be used and \overline{CS} must be taken high after the final clock in order to latch the data.

Stand-Alone Operation

The first falling edge of CS starts the operation cycle. Exactly 24 falling clock edges must be applied before CS is brought back high again. If CS is brought high before the 24th falling SCLK edge, then the data are ignored. If more than 24 falling SCLK edges are applied before \overline{CS} is brought high, then the last 24 bits are considered. The addressed internal register is updated from the Shift Register on the rising edge of CS. In order for another serial transfer to take place, \overline{CS} must be brought low again.

When the data have been transferred into the chosen register of the addressed DAC, all DAC latches and analog outputs can be updated by taking the LDAC pin low or setting the LD bit in the Command Register.

Daisy-Chain Operation

For systems that contain more than one device, the SDO pin can be used to daisy-chain multiple devices together. Daisy-chain operation can be useful in system diagnostics and in reducing the number of serial interface lines. Note that before daisy-chain operation can begin, the SDO pin must be enabled by clearing the SDO disable bit in the Command Register (DSDO ⁼ '0'). By default, this bit is cleared after power-on or reset. The first falling edge of \overline{CS} starts the operation cycle. SCLK is continuously applied to the input shift register when $\overline{\text{CS}}$ is low. If more than 24 clock pulses are applied, the data ripple out of the shift register and appear on the SDO line. These data are clocked out on the rising edge of SCLK and are valid on the falling edge. By connecting the SDO output of the first device to the SDI input of the next device in the chain, ^a multiple-device interface is constructed. Each device in the system requires 24 clock pulses. Therefore, the total number of clock cycles must equal 24 [×] N, where *N* is the total number of DAC7716s in the chain. When the serial transfer to all devices is complete, CS is taken high. This action latches data from the SPI shift register into the device input register of each device in the daisy-chain, and prevents any further data from being clocked in.

SBAS463A–AUGUST 2009–REVISED SEPTEMBER 2009 ... **www.ti.com**

Read-Back Operation

The READ command is used to start read-back operation. However, before read-back operation can be initiated, the SDO pin must be enabled by clearing the DSDO bit in the Command Register (DSDO ⁼ '0'); this bit is cleared by default. Read-back operation is then started by executing a READ command (R/\overline{W} bit = '1'; see [Table](#page-24-0) 2). Bits A3 to A0 in the READ command select the register to be read. The remaining data in the command are *don't care* bits. During the next SPI operation, the data that appear on the SDO output are from the previously addressed register. For ^a read of ^a single register, ^a NOP command can be used to clock out the data from the selected register on SDO. Multiple registers can be read if multiple READ commands are issued. The readback diagram in Figure 43 shows the read-back sequence. The read-back data format is the same format as what was used to write to the device.

Figure 43. Read-Back Operation

SPI SHIFT REGISTER

The SPI Shift Register is 24 bits wide, as shown in Table 2. By default, the SPI shift register resets to 000000h at power-on or after ^a reset.

Table 2. SPI Shift Register Format

(1) Writing to ^a reserved bit has no effect; reading the bit returns '0'.

 R/\overline{W} —Indicates a read from or a write to the addressed register.

 R/\overline{W} = '0' sets a write operation and the data are written to the specified register.

 R/\overline{W} = '1' sets a read-back operation. For read operation, bits A3 to A0 select the register to be read. The remaining are *don't care* bits. During the next SPI operation, the data appearing on SDO pin are from the previously addressed register.

[A3:A0]—Address bits that specify which register is accessed.

DATA—12 data bits

All DAC7716 registers (command registers and data registers) are 16-bit. Table 3 shows the register map.

Table 3. Register Map

(1) Writing to ^a reserved bit has no effect; reading the bit returns '0'.

INTERNAL REGISTERS

The DAC7716 internal registers consist of the Command Register, the Monitor Register, the DAC Input Data Registers, the Zero Registers, and the Gain Registers.

Command Register. Default ⁼ 033Ch.

The Command Register determines the actions performed by the DAC7716.

Table 4. Command Register

[DAC7716](http://focus.ti.com/docs/prod/folders/print/dac7716.html)

Monitor Register. Default = 0000h.

The Monitor Register selects one of the four DAC outputs or the external signal AIN that is to be monitored through the V_{MON} pin. Only one bit can be set to '1' at a time. When all bits = '0', the monitor is disabled and V_{MON} is placed in a high-impedance state. The default value after power-on or reset is 0000h.

Table 5. Monitor Register

(1) Writing to ^a reserved bit has no effect; reading the bit returns '0'.

Input Data Register for DAC-n (where ⁿ ⁼ 0, 1, 2, or 3). Default ⁼ 0000h.

This register stores the DAC data written to the device. When the data are loaded into the corresponding DAC latch, the DAC output changes to the new level defined by the DAC data. The default value after power-on or reset is 0000h.

For bipolar operation, the input data format is always twos complement. For unipolar operation, the input data format is always straight binary.

Table 6. DAC-n (*ⁿ* **⁼ 0, 1, 2, or 3) Input Data Register**

(1) D11:D0 are the DAC data bits.

(2) Writing to ^a reserved bit has no effect; reading the bit returns '0'.

Table 7. DAC Output vs Twos Complement Code for Bipolar Output Operation

Table 8. DAC Output vs Straight Binary Code for Unipolar Output Operation

SBAS463A–AUGUST 2009–REVISED SEPTEMBER 2009 ... **www.ti.com**

Zero Register ⁿ (where ⁿ ⁼ 0, 1, 2, or 3). Default ⁼ 0000h.

The Zero Register stores the user-calibration data that are used to eliminate the offset error. The data are nine bits wide, 0.0078 LSB/step, and the total adjustment is typically -2 LSB to +1.9922 LSB, or ±0.0488% of full-scale range. The Zero Register uses ^a twos complement data format in both bipolar and unipolar modes of operation.

Table 9. Zero Register

(1) Writing to ^a reserved bit has no effect; reading the bit returns '0'.

Gain Register ⁿ (where ⁿ ⁼ 0, 1, 2, or 3). Default ⁼ 0000h.

The Gain Register stores the user-calibration data that are used to eliminate the gain error. The data are eight bits wide, 0.0625 LSB/step, and the total adjustment is typically –8 LSB to +7.9375 LSB, or ±0.195% of full-scale range. The Gain Register uses ^a twos complement data format in both bipolar and unipolar modes of operation.

Table 10. Gain Register

(1) Writing to ^a reserved bit has no effect; reading the bit returns '0'.

www.ti.com... SBAS463A–AUGUST 2009–REVISED SEPTEMBER 2009

APPLICATION INFORMATION

BASIC OPERATION

The DAC7716 is ^a highly-integrated device with high-performance reference buffers and output buffers, greatly reducing the printed circuit board (PCB) area and cost. On-chip reference buffers eliminate the need for ^a negative external reference. Configurable on-chip output buffers support four different output modes. Figure 44 shows ^a basic application for the DAC7716.

The gain bits in the Command Register are: GAIN-0 = '0', GAIN-1 = '1', GAIN-2 = '0', and GAIN-3 = '1'. The DACs are set to the following gains: $DAC-0 = x2$, $DAC-1 = x4$, $DAC-2 = x2$, and $DAC-3 = x4$.

The output ranges are: $\mathsf{V}_{\mathsf{OUT}}\text{-}\mathsf{0}$ = -5V to +5V

 V_{OUT} -1 = $-10V$ to $+10V$, V_{OUT} -2 = 0V to +5V,

SBAS463A–AUGUST 2009–REVISED SEPTEMBER 2009 ... **www.ti.com**

USER ZERO- AND GAIN-CALIBRATION

The DAC7716 is trimmed during production for nominal operating conditions to have very low gain error and offset error. However, to trim the offset and gain errors introduced at other conditions of operation or by other components in the signal chain, the DAC7716 has ^a user zero and gain digital calibration feature for each DAC channel. Figure 45 and Figure 46 illustrate the relationship of zero and gain calibration for the DAC7716 in unipolar output and bipolar output configurations, respectively.

Figure 46. Relationship of Zero and Gain Calibration for ^a Bipolar Output Configuration

(3)

[DAC7716](http://focus.ti.com/docs/prod/folders/print/dac7716.html)

(4)

System Zero Adjust Example

The DAC7716 zero calibration feature can minimize system offset errors to 0.00019% FSR or 38µV over ^a 20V output range. The total adjustment range is approximately ±0.0488% of FSR, or ±9.7mV over a 20V output span.

Assuming that the DAC has been set up with ^a full-scale range of 20V, and the offset error to be eliminated from the signal chain is -1 mV, then the step size = 0.0000019 \times 20V = 38 μ V.

 $-1 \times$ Offset_Error Number of Steps of Zero Calibration = <u>Step Size</u>

Where Offset Error is the value of the offset error to be corrected.

For this example, the number of steps of zero calibration = $1 \text{mV} / 38 \mu\text{V} \approx 26$. Therefore, the Zero Register should be coded with the twos complement of $26 = 000011010$.

Suppose the offset error to be eliminated is +1mV instead; then the number of steps of zero calibration is the twos complement equivalent of –26, which is 1 1110 0110.

System Gain Adjust Example

The DAC7716 gain calibration feature can minimize system gain errors to 0.001525% FSR or 305µV over ^a 20V output range. The total adjustment range is approximately ±0.195% FSR, or –39mV to +38.7mV over ^a 20V output span.

Assuming that the DAC has been set up with ^a full-scale range of 20V, and the gain error to be eliminated from the signal chain is -10 mV, then the step size = 0.00001525 \times 20V = 305 μ V.

 $-1 \times$ Gain_Error Number of Steps of Gain Calibration = The Stam Theorem

Where *Gain_Error* is the value of the gain error to be corrected.

For this example, the number of steps of the gain calibration = $10 \text{mV} / 305 \mu\text{V} \approx 33$. Therefore, the Gain Register should be coded with the twos complement of 33 ⁼ 0010 0001.

Suppose the gain error to be eliminated is +10mV instead; then the number of steps of Gain calibration is the twos complement equivalent of –33, which is 1101 1111.

SBAS463A–AUGUST 2009–REVISED SEPTEMBER 2009 ... **www.ti.com**

LAYOUT AND GROUNDING

Precision analog circuits require careful layout, adequate bypass capacitors, and ^a clean, well-regulated power supply to obtain the best possible dc and ac performance. A careful consideration of the power-supply and ground-return layout helps to ensure the rated performance.

The PCB must be designed so that the analog and digital sections are separated and confined to certain areas of the board. Fast switching signals, such as clocks, must be shielded with the digital ground to avoid radiating noise to other sections of the board, and must never be run near the reference inputs. It is essential to minimize noise on the reference inputs because it couples through to the DAC output. Avoid crossover of digital and analog signals. Traces on opposite sides of the board must run at right angles to each other. This configuration reduces the effects of feedthrough on the board. A microstrip technique may be considered, but may not always be possible with ^a double-sided board. In this technique, the component side of the board is dedicated to the ground plane, and signal traces are placed on the solder side.

DGND is the return path for digital currents and AGND is the analog power ground for the DAC. For the best ac performance, care should be taken to connect DGND and AGND with very low resistance back to the supply ground. If multiple devices require an AGND-to-DGND connection, the connection must be made at one point only. The star ground point must be established as close as possible to the device. Each DAC has ^a ground pin (SGND-x) that must be connected directly to the corresponding reference ground in low-impedance paths to achieve the best performance. SGND-0 and SGND-1 must be connected with REFGND-A, and SGND-2 and SGND-3 must be connected with REFGND-B. It is critical that this trace resistance be extremely small in order to prevent the voltage drops across the path from affecting device linearity and gain performance. The reference ground pins, REFGND-A and REFGND-B, must be connected to analog ground AGND.

POWER-SUPPLY NOISE

The DAC7716 should have ample supply bypassing of 1μ F to 10μ F in parallel with 0.1μ F on each supply, located as close to the package as possible; ideally, placed next to the device. The 1µF to 10µF capacitors must be ^a tantalum-bead type. The 0.1µF capacitor must have low effective series resistance (ESR) and low effective series inductance (ESI), such as common ceramic types that provide ^a low-impedance path to ground at high frequencies to handle transient currents because of internal logic switching. The power-supply lines must use traces as wide as possible to provide low-impedance paths and reduce the effects of glitches on the power-supply line. Apart from these considerations, the wideband noise on the AV_{DD} , AV_{SS}, DV_{DD}, and IOV_{DD} supplies should be filtered before being fed to the DAC in order to obtain the best noise performance possible.

PRECISION VOLTAGE REFERENCE SELECTION

To achieve the optimum performance from the DAC7716 over its full operating temperature range, ^a precision voltage reference must be used. Consideration should be given to the selection of ^a precision voltage reference. The DAC7716 has two reference inputs, REF-A and REF-B. The voltages applied to the reference inputs are used to provide ^a buffered positive and negative reference for the DAC cores. Therefore, any error in the voltage reference is reflected in the outputs of the device. There are four possible sources of error to consider when choosing ^a voltage reference for high-accuracy applications: initial accuracy, temperature coefficient of the output voltage, long-term drift, and output voltage noise. Initial accuracy error on the output voltage of an external reference can lead to ^a full-scale error in the DAC. Therefore, to minimize these errors, ^a reference with ^a low initial accuracy error specification is preferred. Long-term drift is ^a measurement of how much the reference output voltage drifts over time. A reference with ^a tight, long-term drift specification ensures that the overall solution remains relatively stable over its entire lifetime. The temperature coefficient of ^a reference output voltage affects INL, DNL, gain error, and zero error. Choose ^a reference with ^a tight temperature coefficient specification to reduce the dependence of the DAC output voltage on ambient conditions. In high-accuracy applications that have ^a relatively low noise budget, reference output voltage noise must be considered. Choosing ^a reference with as low an output noise voltage as practical for the system resolution required is important. Precision voltage references such as the TI [REF50xx](http://focus-webapps.ti.com/general/docs/sitesearch/searchdevice.tsp;jsessionid=R5BR3WUA5BUK3QC1JAVR3KQ?partNumber=ref50) (2V to 5V) and [REF32xx](http://focus-webapps.ti.com/general/docs/sitesearch/searchdevice.tsp;jsessionid=R5BR3WUA5BUK3QC1JAVR3KQ?partNumber=ref32) (1.25V to 4V), provide low-drift and high-accuracy reference voltage.

PACKAGING INFORMATION

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check<http://www.ti.com/productcontent>for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) Multiple Top-Side Markings will be inside parentheses. Only one Top-Side Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Top-Side Marking for that device.

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

NOTES: A. All linear dimensions are in millimeters

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have *not* been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
