# 捷多邦,专业PCB打样工厂,24小时加急出货 TL783 HIGH-VOLTAGE ADJUSTABLE REGULATOR

SLVS036E - SEPTEMBER 1981 - REVISED FEBRUARY 2000

- Output Adjustable From 1.25 V to 125 V When Used With an External Resistor Divider
- 700-mA Output Current
- Full Short-Circuit, Safe-Operating-Area, and Thermal-Shutdown Protection
- 0.001%/V Typical Input Voltage Regulation
- 0.15% Typical Output Voltage Regulation
- 76-dB Typical Ripple Rejection
- Standard TO-220AB Package

#### description

The TL783 is an adjustable three-terminal high-voltage regulator with an output range of 1.25 V to 125 V and a DMOS output transistor capable of sourcing more than 700 mA. It is

The OUT terminal is in electrical contact with the mounting base.

designed for use in high-voltage applications where standard bipolar regulators cannot be used. Excellent performance specifications, superior to those of most bipolar regulators, are achieved through circuit design and advanced layout techniques.

As a state-of-the-art regulator, the TL783 combines standard bipolar circuitry with high-voltage double-diffused MOS transistors on one chip to yield a device capable of withstanding voltages far higher than standard bipolar integrated circuits. Because of its lack of secondary-breakdown and thermal-runaway characteristics usually associated with bipolar outputs, the TL783 maintains full overload protection while operating at up to 125 V from input to output. Other features of the device include current limiting, safe-operating-area (SOA) protection, and thermal shutdown. Even if ADJ is inadvertently disconnected, the protection circuitry remains functional.

Only two external resistors are required to program the output voltage. An input bypass capacitor is necessary only when the regulator is situated far from the input filter. An output capacitor, although not required, improves transient response and protection from instantaneous output short circuits. Excellent ripple rejection can be achieved without a bypass capacitor at the adjustment terminal.

The TL783C is characterized for operation over the virtual junction temperature range of 0°C to 125°C.

SLVS036E - SEPTEMBER 1981 - REVISED FEBRUARY 2000

#### functional block diagram

#### absolute maximum ratings over operating temperature range (unless otherwise noted)<sup>†</sup>

Input-to-output differential voltage, V <sub>I</sub> – V <sub>O</sub>	125 V
Operating free-air, T <sub>A</sub> ; case, T <sub>C</sub> ; or virtual junction, T <sub>J</sub> , temperature	150°C
Package thermal impedance, $\theta_{JA}$ (see Notes 1 and 2)	22°C/W
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds	260°C
Storage temperature range, T <sub>stg</sub>	°C to 150°C

<sup>†</sup> Stresses beyond those listed under "absolute maximum ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under "recommended operating conditions" is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

- NOTES: 1. Maximum power dissipation is a function of  $T_J(max)$ ,  $\theta_{JA}$ , and  $T_A$ . The maximum allowable power dissipation at any allowable ambient temperature is  $P_D = (T_J(max) T_A)/\theta_{JA}$ . Operating at the absolute maximum  $T_J$  of 150°C can impact reliability. Due to variations in individual device electrical characteristics and thermal resistance, the built-in thermal overload protection may be activated at power levels slightly above or below the rated dissipation.
  - 2. The package thermal impedance is calculated in accordance with JESD 51.

#### recommended operating conditions

SLVS036E - SEPTEMBER 1981 - REVISED FEBRUARY 2000

**TYPICAL CHARACTERISTICS** 

SLVS036E – SEPTEMBER 1981 – REVISED FEBRUARY 2000

#### **TYPICAL CHARACTERISTICS**

#### **DESIGN CONSIDERATIONS**

The internal reference (see functional block diagram) generates 1.25 V nominal (V<sub>ref</sub>) between OUT and ADJ. This voltage is developed across R1 and causes a constant current to flow through R1 and the programming resistor R2, giving an output voltage of:

$$V_{O} = V_{ref} (1 + R2/R1) + I_{I(ADJ)} (R2)$$

or

 $V_{O} \approx V_{ref} (1 + R2/R1)$ 

The TL783 was designed to minimize the input current at ADJ and maintain consistency over line and load variations, thereby minimizing the associated (R2) error term.

To maintain  $I_{I(ADJ)}$  at a low level, all quiescent operating current is returned to the output terminal. This quiescent current must be sunk by the external load and is the minimum load current necessary to prevent the output from rising. The recommended R1 value of 82  $\Omega$  provides a minimum load current of 15 mA. Larger values can be used when the input-to-output differential voltage is less than 125 V (see the output-current curve in Figure 14) or when the load sinks some portion of the minimum current.

SLVS036E - SEPTEMBER 1981 - REVISED FEBRUARY 2000

#### **DESIGN CONSIDERATIONS**

#### bypass capacitors

The TL783 regulator is stable without bypass capacitors; however, any regulator becomes unstable with certain values of output capacitance if an input capacitor is not used. Therefore, the use of input bypassing is recommended whenever the regulator is located more than four inches from the power-supply filter capacitor. A  $1-\mu$ F tantalum or aluminum electrolytic capacitor usually is sufficient.

Adjustment-terminal capacitors are not recommended for use on the TL783 because they can seriously degrade load transient response as well as create a need for extra protection circuitry. Excellent ripple rejection presently is achieved without this added capacitor.

Due to the relatively low gain of the MOS output stage, output voltage dropout may occur under large load transient conditions. The addition of an output bypass capacitor greatly enhances load transient response and prevents dropout. For most applications, it is recommended that an output bypass capacitor be used, with a minimum value of:

$$C_0 (\mu F) = 15/V_0$$

Larger values provide proportionally better transient-response characteristics.

#### protection circuitry

The TL783 regulator includes built-in protection circuits capable of guarding the device against most overload conditions encountered in normal operation. These protective features are current limiting, safe-operating-area protection, and thermal shutdown. These circuits protect the device under occasional fault conditions only. Continuous operation in the current limit or thermal shutdown mode is not recommended.

The internal protection circuits of the TL783 protect the device up to maximum-rated V<sub>I</sub> as long as certain precautions are taken. If V<sub>I</sub> is instantaneously switched on, transients exceeding maximum input ratings may occur, which can destroy the regulator. These are usually caused by lead inductance and bypass capacitors causing a ringing voltage on the input. In addition, when rise times in excess of 10 V/ns are applied to the input, a parasitic npn transistor in parallel with the DMOS output can be turned on, causing the device to fail. If the device is operated over 50 V and the input is switched on rather than ramped on, a low-Q capacitor, such as tantalum or aluminum electrolytic should be used rather than ceramic, paper, or plastic bypass capacitors. A Q factor of 0.015 or greater usually provides adequate damping to suppress ringing. Normally, no problems occur if the input voltage is allowed to ramp upward through the action of an ac line rectifier and filter network.

Similarly, when an instantaneous short circuit is applied to the output, both ringing and excessive fall times can result. A tantalum or aluminum electrolytic bypass capacitor is recommended to eliminate this problem. However, if a large output capacitor is used and the input is shorted, addition of a protection diode may be necessary to prevent capacitor discharge through the regulator. The amount of discharge current delivered is dependent on output voltage, size of capacitor, and fall time of V<sub>I</sub>. A protective diode (see Figure 17) is required only for capacitance values greater than:

 $C_0 (\mu F) = 3 \times 10^4 / (V_0)^2$ 

Care always should be taken to prevent insertion of regulators into a socket with power on. Power should be turned off before removing or inserting regulators.

SLVS036E – SEPTEMBER 1981 – REVISED FEBRUARY 2000

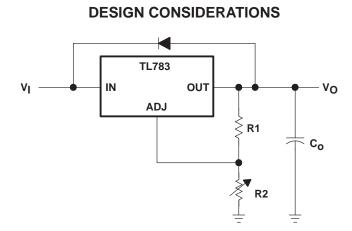

Figure 15. Regulator With Protective Diode

### load regulation

The current-set resistor (R1) should be located close to the regulator output terminal rather than near the load. This eliminates long line drops from being amplified, through the action of R1 and R2, to degrade load regulation. To provide remote ground sensing, R2 should be near the load ground.
