

Positive High Voltage Hot Swap Controller

August 1999

FEATURES

- Allows Safe Board Insertion and Removal from a Live Backplane
- Controls Supply Voltage from 9V to 80V
- Programmable Analog Foldback Current Limiting
- High Side Drive for an External N-Channel
- Automatic Retry or Latched Operation Mode
- User Programmable Supply Voltage Power-Up Rate
- Undervoltage Lockout
- Overvoltage Protection

APPLICATIONS

- Hot Board Insertion
- Electronic Circuit Breaker
- Industrial High Side Switch/Circuit Breaker
- 24V/48V Industrial/Alarm Systems

DESCRIPTION

The LT[®]1641 is an 8-pin Hot Swap[™] controller that allows a board to be safely inserted and removed from a live backplane. Using an external N-channel pass transistor, the board supply voltage can be ramped up at a programmable rate. A high side switch driver controls an N-channel gate for supply voltages ranging from 9V to 80V.

The chip features a programmable analog foldback current limit circuit. If the chip remains in current limit for more than a programmable time, the N-channel pass transistor latches off and is optionally set to automatically restart after a time-out delay.

The PWRGD output indicates when the output voltage, sensed by the FB pin, is within tolerance. The ON pin provides programmable undervoltage lockout.

The LT1641 is available in the 8-lead SO package.

LT, LTC and LT are registered trademarks of Linear Technology Corporation.
Hot Swap is a trademark of Linear Technology Corporation.

Note 1: Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.

Note 2: All currents into device pins are positive; all currents out of device pins are negative. All voltages are referenced to ground unless otherwise specified.

PIN FUNCTIONS

ON (Pin 1): The ON pin is used to implement undervoltage lockout. When the ON pin is pulled below the 1.233V High-to-Low threshold voltage, an undervoltage condition is detected and the GATE pin is pulled low to turn the MOSFET off. When the ON pin rises above the 1.313V Low-to-High threshold voltage, the MOSFET is turned on again.

Pulsing the ON pin low after a current limit fault will reset the fault latch and allow the part to turn back on.

FB (Pin 2): “Power Good” Comparator Input. It monitors the output voltage with an external resistive divider. When the voltage on the FB pin is lower than the High-to-Low threshold of 1.233V, the PWRGD pin is pulled low and released when the FB pin is pulled above the 1.313V Low-to-High threshold.

The FB pin also effects foldback current limit (see Figure 7 and related discussion).

PWRGD (Pin 3): Open Collector Output to GND. The PWRGD pin is pulled low whenever the voltage at the FB pin falls below the High-to-Low threshold voltage. It goes into a high impedance state when the voltage on the FB pin exceeds the Low-to-High threshold voltage. An external pull-up resistor can pull the pin to a voltage higher or lower than V_{CC} .

GND (Pin 4): Chip Ground.

TIMER (Pin 5): Timing Input. An external timing capacitor at this pin programs the maximum time the part is allowed to remain in current limit.

When the part goes into current limit, an 80 μA pull-up

current source starts to charge the timing capacitor. When the voltage on the TIMER pin reaches 1.233V, the GATE pin is pulled low; the pull-up current will be turned off and the capacitor is discharged by a 3 μA pull-down current. When the TIMER pin falls below 0.5V, the GATE pin turns on once the ON pin is pulsed low to reset the internal fault latch. If the ON pin is not cycled low, the GATE pin remains latched off.

By connecting a 0.01 μF capacitor from the GATE pin to the center tap of a resistive divider at the ON pin, the part automatically restarts after a current limit fault. With a short at the output, the part cycles on and off with a 3.75% on-time duty cycle.

GATE (Pin 6): The High Side Gate Drive for the External N-Channel. An internal charge pump guarantees at least 10V of gate drive for supply voltages above 20V and 4.5V gate drive for supply voltages between 9V and 20V. The rising slope of the voltage at the GATE is set by an external capacitor connected from the GATE pin to GND and an internal 10 μA pull-up current source from the charge pump output.

When the current limit is reached, the GATE pin voltage will be adjusted to maintain a constant voltage across the sense resistor while the timer capacitor starts to charge. If the TIMER pin voltage exceeds 1.233V, the GATE pin will be pulled low.

The GATE pin is pulled to GND whenever the ON pin is pulled low, the V_{CC} supply voltage drops below the 8.3V undervoltage lockout threshold or the TIMER pin rises above 1.233V.

LT1641

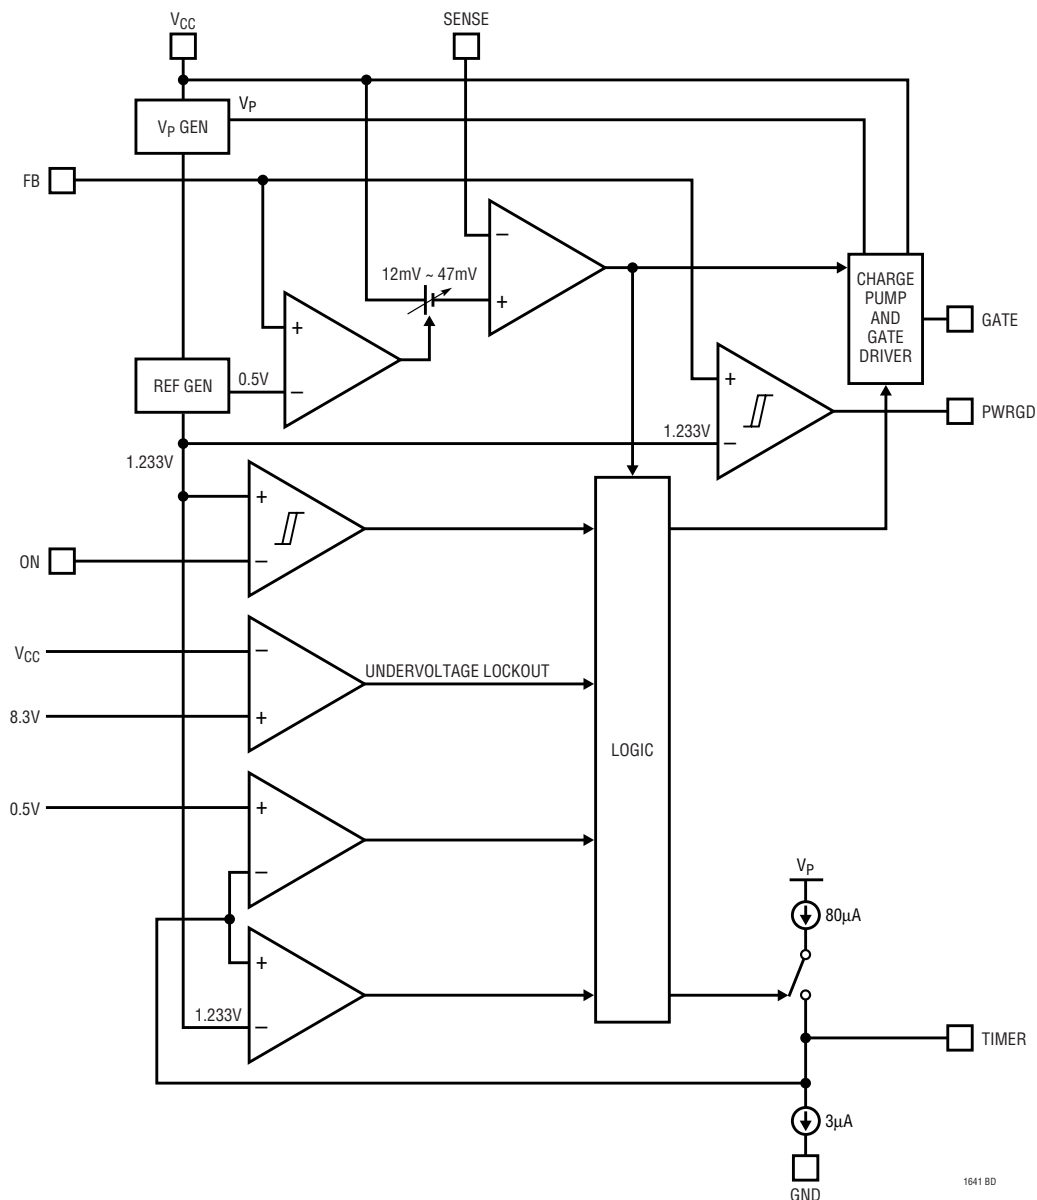

PIN FUNCTIONS

SENSE (Pin 7): The Current Limit Sense Pin. A sense resistor must be placed in the supply path between V_{CC} and SENSE. The current limit circuit will regulate the voltage across the sense resistor ($V_{CC} - V_{SENSE}$) to 47mV when V_{FB} is 0.5V or higher. If V_{FB} drops below 0.5V, the voltage across the sense resistor decreases linearly and stops at 12mV when V_{FB} is 0V.

To defeat current limit, short the SENSE pin to the V_{CC} pin.

V_{CC} (Pin 8): The Positive Supply Input ranges from 9V to 80V for normal operation. I_{CC} is typically 2mA. An internal undervoltage lockout circuit disables the chip for inputs less than 8.3V. Place a 0.1 μ F bypass capacitor next to the V_{CC} pin.

APPLICATIONS INFORMATION

Hot Circuit Insertion

When circuit boards are inserted into a live backplane, the supply bypass capacitors on the boards draw high peak currents from the backplane power bus as they charge up. The transient currents can permanently damage the connector pins and glitch the system supply, causing other boards in the system to reset.

The LT1641 is designed to turn on a board's supply voltage in a controlled manner, allowing the board to be safely inserted or removed from a live backplane. The chip also provides undervoltage and overcurrent protection while a power good output signal indicates when the output supply voltage is ready.

Power-Up Sequence

The power supply on a board is controlled by placing an external N-channel pass transistor (Q1) in the power path (Figure 5). Resistor R_S provides current detection and capacitor C1 provides control of the GATE slew rate.

Resistor R6 provides current control loop compensation while R5 prevents high frequency oscillations in Q1. Resistors R1 and R2 provide undervoltage sensing.

After the power pins first make contact, transistor Q1 is turned off. If the voltage at the ON pin exceeds the turn-on threshold voltage, the voltage on the V_{CC} pin exceeds the undervoltage lockout threshold, and the voltage on the TIMER pin is less than 1.233V, transistor Q1 will be turned on (Figure 6). The voltage at the GATE pin rises with a slope equal to $10\mu\text{A}/\text{C1}$ and the supply inrush current is set at $I_{\text{INRUSH}} = C_L \cdot 10\mu\text{A}/\text{C1}$. If the voltage across the current sense resistor R_S gets too high, the inrush current will then be limited by the internal current limit circuitry which adjusts the voltage on the GATE pin to maintain a constant voltage across the sense resistor.

Once the voltage at the output has reached its final value, as sensed by resistors R3 and R4, the PWRGD pin goes high.

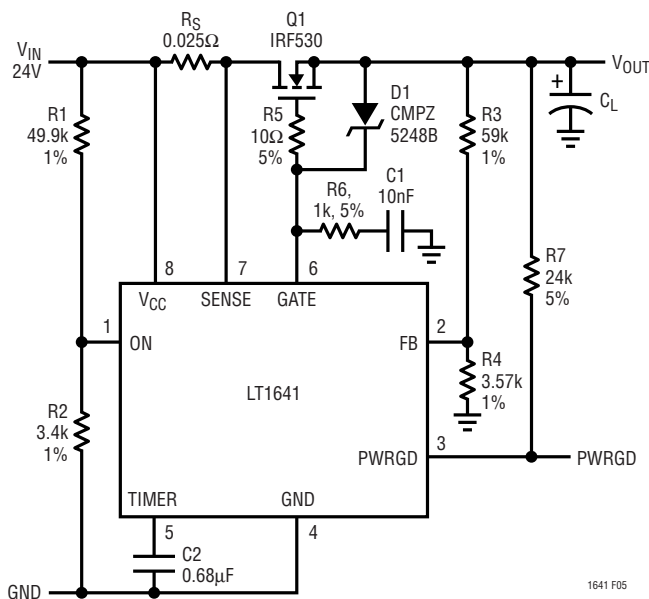

Figure 5. Typical Application

Figure 6. Power-Up Waveforms

APPLICATIONS INFORMATION

Short-Circuit Protection

The LT1641 features a programmable foldback current limit with an electronic circuit breaker that protects against short-circuits or excessive supply currents. The current limit is set by placing a sense resistor between V_{CC} (Pin 8) and SENSE (Pin 7).

To prevent excessive power dissipation in the pass transistor and to prevent voltage spikes on the input supply during short-circuit conditions at the output, the current folds back as a function of the output voltage, which is sensed at the FB pin (Figure 7).

When the voltage at the FB pin is 0V, the current limit circuit drives the GATE pin to force a constant 12mV drop across the sense resistor. As the output voltage at the FB pin increases, the voltage across the sense resistor increases until the FB pin reaches 0.5V, at which point the voltage across the sense resistor is held constant at 47mV.

Figure 7. Current Limit Sense Voltage vs Feedback Pin Voltage

The maximum current limit is calculated as:

$$I_{LIMIT} = 47\text{mV}/R_{SENSE}$$

For a 0.025Ω sense resistor, the current limit is set at 1.88A and folds back to 480mA when the output is shorted to ground.

The LT1641 also features a variable overcurrent response time. The time required for the chip to regulate the GATE pin (Pin 6) voltage is a function of the voltage across the sense resistor connected between the V_{CC} pin (Pin 8) and the SENSE pin (Pin 7). The larger the voltage, the faster the gate will be regulated. Figure 8 shows the response time as a function of overdrive at the SENSE pin.

Figure 8. Response Time to Overcurrent

APPLICATIONS INFORMATION

TIMER

The TIMER pin (Pin 5) provides a method for programming the maximum time the chip is allowed to operate in current limit. When the current limit circuitry is not active, the TIMER pin is pulled to GND by a $3\mu\text{A}$ current source. After the current limit circuit becomes active, an $80\mu\text{A}$ pull-up current source is connected to the TIMER pin and the voltage will rise with a slope equal to $77\mu\text{A}/C_{\text{TIMER}}$ as long as the current limit circuit remains active. Once the desired maximum current limit time is set, the capacitor value is: $C(\text{nF}) = 62 \cdot t(\text{ms})$.

If the current limit circuit turns off, the TIMER pin will be discharged to GND by the $3\mu\text{A}$ current source.

Whenever the TIMER pin reaches 1.233V, the internal fault latch is set. The GATE pin is immediately pulled to GND and the TIMER pin is pulled back to GND by the $3\mu\text{A}$ current source. The part is not allowed to turn on again until the voltage at the TIMER pin falls below 0.5V. The fault latch is cleared by pulling the ON pin low.

The waveform in Figure 9 shows how the output latches off following a short-circuit. The drop across the sense resistor is held at 12mV as the timer ramps up. Since the output did not rise bringing FB above 0.5V, the circuit latches off.

Automatic Restart

To force the LT1641 to automatically restart after an overcurrent fault, the bottom plate of capacitor C1 can be tied back to the ON pin (Figure 10).

Figure 9. Short-Circuit Waveforms

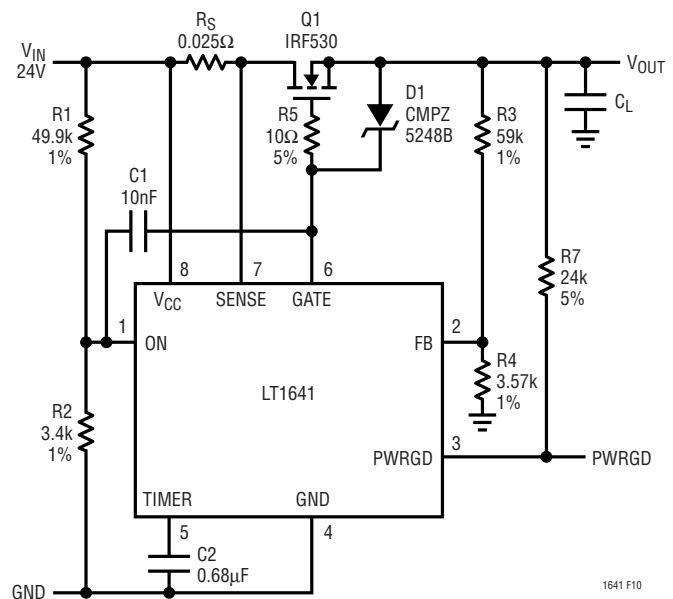

Figure 10. Automatic Restart Application

APPLICATIONS INFORMATION

When an overcurrent condition occurs, the GATE pin is driven to maintain a constant voltage across the sense resistor. The capacitor C2 at the TIMER pin will begin to charge. When the voltage at the TIMER pin reaches 1.233V, the GATE pin is immediately pulled to GND and transistor Q1 turns off. Capacitor C1 momentarily pulses the ON pin low and clears the internal fault latch. When the voltage at the TIMER pin ramps back down to 0.5V, the LT1641 turns on again. If the short-circuit condition at the output still exists, the cycle will repeat itself indefinitely with a 3.75% on-time duty cycle which prevents Q1 from overheating. The waveforms are shown in Figure 11.

Figure 11. Automatic Restart Waveforms

Undervoltage and Overvoltage Detection

The ON pin can be used to detect an undervoltage condition at the power supply input. The ON pin is internally connected to an analog comparator with 80mV of hysteresis. If the ON pin falls below its threshold voltage (1.233V), the GATE pin is pulled low and is held low until ON is high again.

Figure 12 shows an overvoltage detection circuit. When the input voltage exceeds the Zener diode's breakdown voltage, D1 turns on and starts to pull the TIMER pin high.

After the TIMER pin is pulled higher than 1.233V, the fault latch is set and the GATE pin is pulled to GND immediately, turning off transistor Q1. The waveforms are shown in Figure 13. Operation is restored either by interrupting power or by pulsing ON low.

Figure 12. Overvoltage Detection

Figure 13. Overvoltage Waveforms

LT1641

APPLICATIONS INFORMATION

Power Good Detection

The LT1641 includes a comparator for monitoring the output voltage. The noninverting input (FB pin) is compared against an internal 1.233V precision reference and exhibits 80mV hysteresis. The comparator's output (PWRGD pin) is an open collector capable of operating from a pull-up as high as 100V.

The PWRGD pin can be used to directly enable/disable a power module with an active high enable input. Figure 14 shows how to use the PWRGD pin to control an active low enable input power module. Signal inversion is accomplished by transistor Q2 and R7.

Supply Transient Protection

The LT1641 is 100% tested and guaranteed to be safe from damage with supply voltages up to 100V. However, spikes above 100V may damage the part. During a short-circuit condition, the large change in currents flowing through the power supply traces can cause inductive voltage spikes which could exceed 100V. To minimize the spikes, the power trace parasitic inductance should be minimized by using wider traces or heavier trace plating and a 0.1 μ F bypass capacitor placed between V_{CC} and GND. A surge suppressor at the input can also prevent damage from voltage surges.

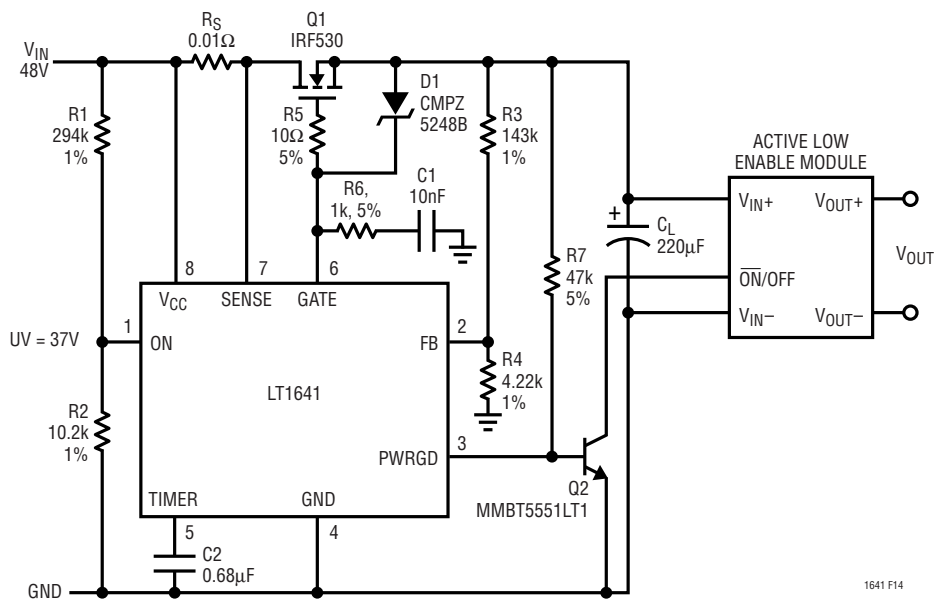

Figure 14. Active Low Enable Module

1641 F14

APPLICATIONS INFORMATION

GATE Pin Voltage

A curve of gate drive vs V_{CC} is shown in Figure 15. The GATE pin is clamped to a maximum voltage of 18V above the input voltage. At minimum input supply voltage of 9V, the minimum gate drive voltage is 4.5V. When the input supply voltage is higher than 20V, the gate drive voltage is at least 10V and a regular N-FET can be used. In applications ranges 9V to 24V range, a logic level N-FET must be used with a proper protection Zener diode between its gate and source (as D1 shown in Figure 5).

1641 F15

Figure 15. Gate Drive vs Supply Voltage

Layout Considerations

To achieve accurate current sensing, a Kelvin connection is recommended. The minimum trace width for 1oz copper foil is 0.02" per amp to make sure the trace stays at a reasonable temperature. 0.03" per amp or wider is recommended. Note that 1oz copper exhibits a sheet resistance of about $530\mu\Omega/\square$. Small resistances add up quickly in high current applications. To make the system immune to noise, the resistor divider to the ON pin needs to be close to the chip and keep traces to V_{CC} and GND short. A $0.1\mu F$ capacitor from the ON pin to GND also helps reject induced noise. Figure 16 shows a layout that addresses these issues.
