Two-Channel, Triple/Quad RGB Video Switches and Buffers

General Description

The MAX463–MAX470 series of two-channel, triple/quad buffered video switches and video buffers combines high-accuracy, unity-gain-stable amplifiers with high-performance video switches. Fast switching time and low differential gain and phase error make this series of switches and buffers ideal for all video applications. The devices are all specified for \pm 5V supply operation with inputs and outputs as high as \pm 2.5V when driving 150 Ω loads (75 Ω back-terminated cable).

Input capacitance is typically only 5pF, and channel-tochannel crosstalk is better than 60dB, accomplished by surrounding all inputs with AC ground pins. The onboard amplifiers feature a 200V/µs slew rate (300V/µs for A_V = 2V/V amplifiers), and a bandwidth of 100MHz (90MHz for A_V = 2V/V buffers). Channel selection is controlled by a single TTL-compatible input pin or by a microprocessor interface, and channel switch time is only 20ns.

For design flexibility, devices are offered with bufferamplifier gains of 1V/V or 2V/V for 75 Ω back-terminated applications. Output amplifiers have a guaranteed output swing of ±2V into 75 Ω .

Typical Operating Circuit appears at end of data sheet.

- _____Features
- 100MHz Unity-Gain Bandwidth
- 90MHz Bandwidth with 2V/V Gain
- 0.01%/0.03° Differential Gain/Phase Error
- + Drives 50 Ω and 75 Ω Back-Terminated Cable Directly
- Wide Output Swing: ±2V into 75Ω ±2.5V into 150Ω
- ♦ 300V/µs Slew Rate (2V/V gain)
- 20ns Channel Switching Time
- Logic Disable Mode: High-Z Outputs
- Reduced Power Consumption + Outputs May Be Paralleled for Larger Networks
- 5pF Input Capacitance (channel on or off)

MAX463-MAX470

_Detailed Description

The MAX463–MAX470 have a bipolar construction, which results in a typical channel input capacitance of only 5pF, whether the channel is on or off. This low input capacitance allows the amplifiers to realize full AC performance, even with source impedances as great as 250Ω . It also minimizes switching transients because the driving source sees the same load whether the channel is on or off. Low input capacitance is critical, because it forms a single-pole RC low-pass filter with the output impedance of the signal source, and this filter can limit the system's signal bandwidth if the RC product becomes too large.

The MAX465/MAX466/MAX469/MAX470's amplifiers are internally configured for a gain of two, resulting in an overall gain of one at the cable output when driving back-terminated coaxial cable (see the section *Driving Coaxial Cable*). The MAX463/MAX464/MAX467/MAX468 are internally configured for unity gain.

Power-Supply Bypassing and Board Layout

To realize the full AC performance of high-speed amplifiers, pay careful attention to power-supply bypassing and board layout, and use a large, low-impedance ground plane. With multi-layer boards, the ground plane should be located on the layer that is not dedicated to a specific signal trace.

To prevent unwanted signal coupling, minimize the trace area at the circuit's critical high-impedance nodes, and surround the analog inputs with an AC ground trace (analog ground, bypassed DC power supply, etc). The analog input pins to the MAX463-MAX470 have been separated with AC ground pins (GND, V+, V-, or a hard-wired logic input) to minimize parasitic coupling, which can degrade crosstalk and/or stability of the amplifier. Keep signal paths as short as possible to minimize inductance, and ensure that all input channel traces are of equal length to maintain the phase relationship between the R, G, and B signals. Connect the coaxial-cable shield to the ground side of the 75Ω terminating resistor at the ground plane to further reduce crosstalk (see Figure 1).

Bypass all power-supply pins directly to the ground plane with $0.1\mu F$ ceramic capacitors, placed as close to the supply pins as possible. For high-current loads, it may be necessary to include $10\mu F$ tantalum or aluminum-electrolytic capacitors in parallel with the $0.1\mu F$ ceramics. Keep capacitor lead lengths as short as possible to minimize series inductance; surface-mount (chip) capacitors are ideal.

Figure 1. Low-Crosstalk Layout. Return current from the termination resistor does not flow through the ground plane.

Connect all V- pins to a large power plane. The V- pins conduct heat away from the internal die, aiding thermal dissipation.

Differential Gain and Phase Errors

Differential gain and phase errors are critical specifications for an amplifier/buffer in color video applications, because these errors correspond directly to changes in the color of the displayed picture in composite video systems. The MAX467–MAX470 have low differential gain and phase errors, making them ideal in broadcastquality composite color applications, as well as in RGB video systems where these errors are less significant.

The MAX467–MAX470 differential gain and phase errors are measured with the Tektronix VM700 Video Measurement Set, with the input test signal provided by the Tektronix 1910 Digital Generator as shown in Figure 2.

Measuring the differential gain and phase of the MAX469/MAX470 (Figure 2a) is straightforward because the output amplifiers are configured for a gain of two, allowing connection to the VM700 through a back-terminated coaxial cable. Since the MAX467/MAX468 are unity-gain devices, driving a back-terminated coax would result in a gain of 1/2 at the VM700.

Figure 2b shows a test method to measure the differential gain and phase for the MAX467/MAX468. First, measure and store the video signal with the device under test (DUT) removed and replaced with a short circuit, and the 150Ω load resistor omitted. Then do another measurement with the DUT and load resistor in the circuit, and calculate the differential gain and phase errors by subtracting the results.

Figure 2. Differential Phase and Gain Error Test Circuits (a) for the MAX469/MAX470 Gain-of-Two Amplifiers, (b) for the MAX467/MAX468 Unity-Gain Amplifiers

Driving Coaxial Cable

High-speed performance, excellent output current capability, and an internally fixed gain of two make the MAX465/MAX466/MAX469/MAX470 ideal for driving 50 Ω or 75 Ω back-terminated coaxial cables. The MAX465/MAX466/MAX469/MAX470 will drive a 150 Ω load (75 Ω back-terminated cable) to ±2.5V.

The *Typical Operating Circuit* shows the MAX465/MAX466 driving four back-terminated 75 Ω video cables. The back-termination resistor (at each amplifier output) provides impedance matching at the driven end of the cable to eliminate signal reflections. It forms a voltage divider with the load impedance, which attenuates the signal at the cable output by one-half. The amplifier operates with an internal 2V/V closed-loop gain to provide unity gain at the cable's output.

Driving Capacitive Loads

Driving large capacitive loads increases the likelihood of oscillation in most amplifier circuits. This is especially true for circuits with high loop-gains, like voltage followers. The amplifier's output impedance and the capacitive load form an RC filter that adds a pole to the loop response. If the pole frequency is low enough, as when driving a large capacitive load, the circuit phase margin is degraded and oscillation may occur. The MAX463–MAX470 phase margin and capacitiveload driving performance are optimized by internal compensation. When driving capacitive loads greater than 50pF, connect an isolation resistor between the amplifier output and the capacitive load, as shown in Figure 3.

Figure 3a. Using an Isolation Resistor with a Capacitive Load

M/IXI/N

MAX463-MAX470

Figure 3b. Step Response without an Isolation Resistor

Digital Interface

The MAX463–MAX466 multiplexer architecture provides an input transistor buffer, ensuring that no input channels are ever connected together. Select a channel by changing A0's state (A0 = 0 for channel A, and A0 = 1 for channel B) and pulsing \overline{CS} low (see Tables 1a, 1b). Figure 4 shows the logic timing diagram.

Output Disable (MAX463–MAX466)

When the enable input (\overline{EN}) is driven to a TTL low state, it enables the MAX463–MAX466 amplifier outputs. When \overline{EN} is driven high, it disables the amplifier outputs. The

Figure 3c. Step Response with an Isolation Resistor

disabled MAX463/MAX464 outputs exhibit a 250k Ω typical resistance. Because their internal feedback resistors are required to produce a gain of two, the MAX465/MAX466 exhibit a 1k Ω disabled output resistance.

LE determines whether $\overline{\text{EN}}$ is latched by $\overline{\text{CS}}$ or operates independently. When the latch-enable input (LE) is connected to V+, $\overline{\text{CS}}$ becomes the latch control for the $\overline{\text{EN}}$ input register. If $\overline{\text{CS}}$ is low, both the $\overline{\text{EN}}$ and A0 registers are transparent; once $\overline{\text{CS}}$ returns high, both registers are latched.

Figure 4. Logic Timing Diagram

M/XI/M

Table 1a. Amplifier and Channel Selection with LE = V+

ĊS	ĒŇ	A0	FUNCTION	
0	0	0	Enables amplifier outputs. Selects channel A.	
0	0	1	Enables amplifier outputs. Selects channel B.	
0	1	Х	Disables amplifiers. Outputs high-Z.	
1	Х	Х	Latches all input registers. Changes nothing.	

Table 1b. Amplifier and Channel Selection with LE = GND

CS	ĒÑ	A0	FUNCTION	
0	0	0	Enables amplifier outputs. Selects channel A.	
0	0	1	Enables amplifier outputs. Selects channel B.	
0	1	0	Disables amplifiers. Outputs high-Z. A0 register = channel A	
0	1	1	Disables amplifiers. Outputs high-Z. A0 register = channel B	
1	0	х	Enables amplifier outputs, latches A0 register, programs outputs to output A or B, according to the setting of A0 at CS's last edge.	
1	1	Х	Disables amplifiers. Outputs high-Z.	

When LE is connected to ground, the \overline{EN} register is transparent and independent of \overline{CS} activity. This allows all MAX463–MAX466 devices to be simultaneously shut down, regardless of the \overline{CS} input state. Simply connect LE to ground and connect all \overline{EN} inputs together (Figure 5a). For the MAX464 and MAX466, LE must be hardwired to either V+ or ground (rather than driving LE with a gate) to prevent crosstalk from the digital inputs to INOA.

Another option for output disable is to connect LE to V+, parallel the outputs of several MAX463-MAX466s, and use EN to individually disable all devices but the one in use (Figure 5b).

When the outputs are disabled, the off isolation from the analog inputs to the amplifier outputs is typically 70dB at 10MHz, all inputs driven with a 4VP-P sine wave and a 150 Ω load impedance. Figure 6 shows the test circuits used to measure isolation and crosstalk.

Applications Information

Higher-Order RGB + Sync Video Multiplexing

Higher-order RGB video multiplexers can be realized by paralleling several MAX463/MAX464s. Connect LE to V+ and use \overline{CS} and \overline{EN} to disable all devices but the one in use. Since the disabled output resistance of the MAX463/MAX464 is 250k Ω , several devices may be paralleled to form larger RGB video multiplexer arrays without signal degradation. Connect series resistors at each amplifier's output to isolate the disabled output capacitance of each paralleled device, and use a MAX469 or MAX470 to drive the output coaxial cables (see Figure 7).

Paralleling MAX466s to Switch 1-of-4 RGB + Sync Signal Inputs

Figure 8 shows a 1-of-4 RGB + sync video mux/amp circuit. The 1k Ω disabled output resistance limits the number of paralleled MAX465/MAX466s to no more than two. The amplifier outputs are connected after a 22 Ω isolation resistor and ahead of a 50 Ω back-termination resistor, which isolates the active amplifier output from the capacitive load (5pF typ) presented by the inactive output of the second MAX466. Impedance mismatching is minimal, and the signal gain at the cable end is near 1. This minimizes ringing in the output signals. For multiplexing more than two devices, see the section *Higher Order RGB + Sync Video Multiplexing*, above.
