Caution: These CMOS devices have input static protection (Class 2) but are still susceptible to damage when exposed to extremely high static electrical charges.

Intended for use in ink-jet printer applications, the A6817SEP addressable 28-line decoder/driver combines low-power CMOS inputs and logic with 28 high-current, high-voltage bipolar outputs. A 4-to-14 line decoder determines the selected output driver (n) in each 14-driver bank. Two independent output-enable inputs (active low) then provide the final decoding to activate 1- or 2-of-28 outputs (OUT_{An} and/or OUT_{Bn}). Special internal circuitry is programmed at the time of manufacture to adjust the output pulse timing and thereby the energy the device delivers to the ink-jet print head. The DABiC-IV A6817SEP directly replaces the original BiMOS-II A5817SEP in most applications.

The CMOS inputs cause minimal loading and are compatible with standard CMOS, PMOS, and NMOS logic. Use with TTL or DTL circuits may require appropriate pull-up resistors to ensure an input logic high. The internal CMOS logic operates from a 5 V supply. A CHIP ENABLE function is provided to lock out the drivers during system power up. The 28 bipolar power outputs are open-collector 30 V Darlington drivers capable of sinking 500 mA at ambient temperatures up to 85°C.

The A6817SEP is furnished in a 44-lead plastic chip carrier (quad pack) for minimum-area, surface-mount applications.

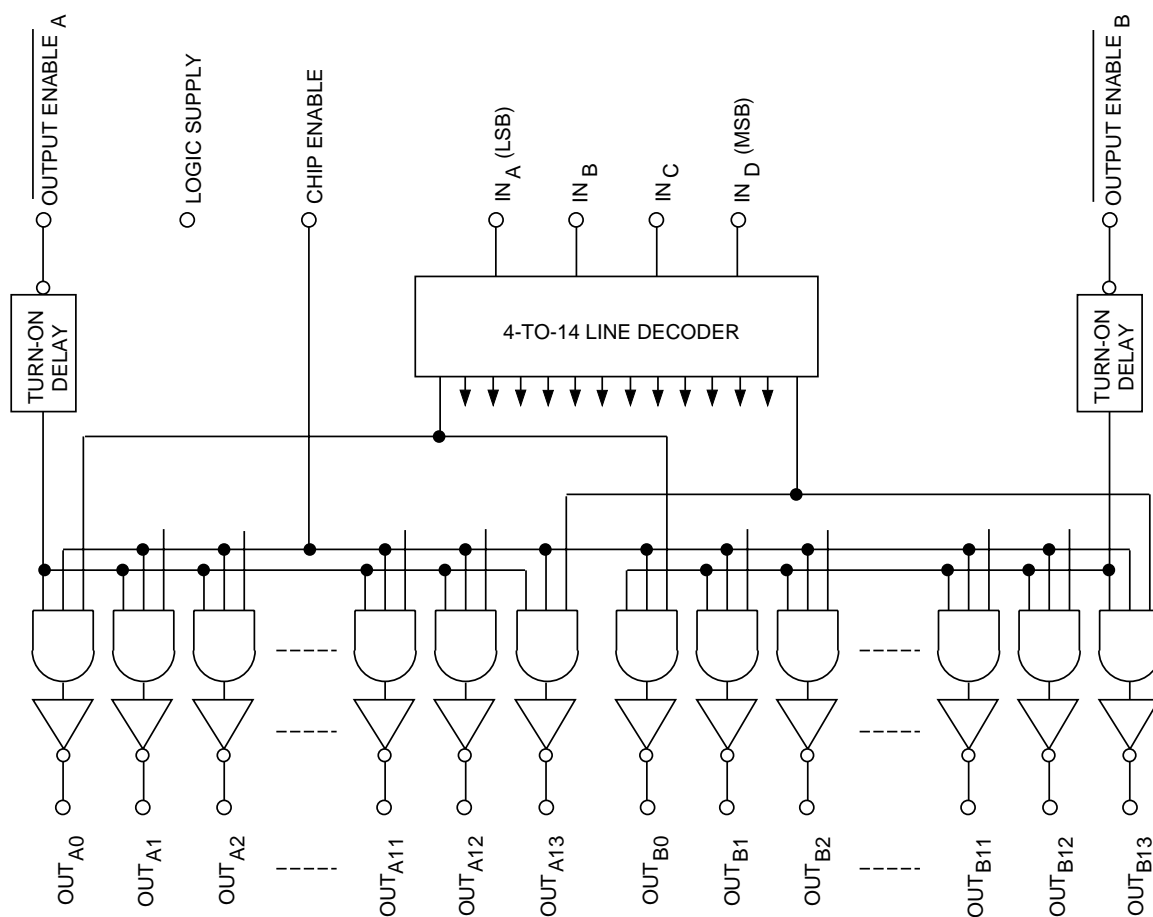

FEATURES

- Controlled Characteristics for Ink-Jet Printers
- Addressable Data Entry
- 30 V Minimum $V_{(BR)CEX}$
- CMOS, PMOS, NMOS Compatible Inputs
- Low-Power CMOS Logic

Always order by complete part number: **A6817SEP**.

APPLICATIONS INFORMATION

This device is intended specifically for, although certainly not limited to, driving ink-jet print heads. In this application, a certain minimum energy (a function of load voltage and output pulse duration) is required for proper operation, while excessive energy will degrade the life of the print head. The output pulse duration (t_{OUT}) is equal to $t_{ENABLE} + t_{PLH} - t_{PHL}$, where t_{PHL} is adjusted during manufacture to compensate for variations in the output saturation voltage ($V_{CE(SAT)}$).

For the A6817SEP, the relationship between t_{OUT} and t_{ENABLE} at $T_A = 25^\circ\text{C}$ is:

$$t_{OUT} = t_{ENABLE} ([V_{CE(SAT)}(\text{actual}) - V_{CE(SAT)}(\text{typical})] \times 330 \text{ ns}) + 25 \text{ ns} + 110 \text{ ns}.$$

For most applications, this will result in a driver-contribution-to-energy-error of less than $\pm 4\%$.

A logic low on the CHIP ENABLE input will prevent the drivers from turning ON, regardless of the state of other inputs or the logic supply voltage. The CHIP ENABLE input has a slow response time and should not be used as a high-speed control line. For proper operation, all ground terminals should be connected to a common ground on the printed wiring board. The IC (Internal Connection) terminals are used to program the turn-on time of the device and **MUST** be left electrically unconnected (floating) for proper operation.

Depending on the four address inputs, the 4-to-14 line decoder selects one driver from each of the 14 output A and B banks of sink drivers according to the Decoder Truth Table. The state of the selected outputs is determined by the OUTPUT ENABLE inputs as shown in the Enable Truth Table.
