

# MAXIM

## ***μP Compatible 8 Bit A/D Converter***

### **General Description**

The MAX160 and MX7574 are low cost, microprocessor compatible 8 bit analog-to-digital converters which use the successive-approximation technique to achieve conversion times of 4 $\mu$ s (MAX160) and 15 $\mu$ s (MX7574).

The A/Ds are designed to easily interface with microprocessors by appearing as a memory location or I/O port without the need for external interfacing logic. Data outputs use latched, three-state buffer circuitry to allow direct connection to a microprocessor data bus or system input port. Operation is simplified by an on-chip clock, +5V power supply requirement, and low supply current (5mA max).

The MAX160 provides major performance improvements over the AD7574 in accuracy and speed specifications as well as compatibility with TTL logic levels.

### **Applications**

- Digital Signal Processing
- High Speed Data Acquisition
- Telecommunications
- Process Automation
- Instrumentation
- Avionics

### **Functional Diagram**

### **Features**

- ◆ Improved Second Source (MAX160)
- ◆ Fast Conversion Time: 4 $\mu$ s (MAX160)  
15 $\mu$ s (MX7574)
- ◆ No Missing Codes Over Temperature
- ◆ Single +5V Supply
- ◆ Ratiometric Operation
- ◆ No External Clock Necessary
- ◆ Easy Interface To Microprocessors

### **Ordering Information**

PART	TEMP. RANGE	PACKAGE†	ERROR
MAX160CPN	0°C to +70°C	Plastic DIP	$\pm\frac{1}{2}$ LSB
MAX160CC/D	0°C to +70°C	Dice*	$\pm\frac{1}{2}$ LSB
MAX160CWN	0°C to +70°C	Small Outline	$\pm\frac{1}{2}$ LSB
MAX160EPN	-40°C to +85°C	Plastic DIP	$\pm\frac{1}{2}$ LSB
MAX160EWN	-40°C to +85°C	Small Outline	$\pm\frac{1}{2}$ LSB
MAX160MJN	-55°C to +125°C	CERDIP**	$\pm\frac{1}{2}$ LSB
MX7574KN	0°C to +70°C	Plastic DIP	$\pm\frac{1}{2}$ LSB
MX7574JN	0°C to +70°C	Plastic DIP	$\pm\frac{3}{4}$ LSB
MX7574KCWN	0°C to +70°C	Small Outline	$\pm\frac{1}{2}$ LSB
MX7574JCWN	0°C to +70°C	Small Outline	$\pm\frac{3}{4}$ LSB

† All devices — 18 lead packages

\* Consult factory for dice specifications.

\*\* Maxim reserves the right to ship Ceramic Packages in lieu of CERDIP packages.

### **ABSOLUTE MAXIMUM RATINGS — MAX160, MX7574**

Supply Voltage, $V_{DD}$ to AGND	0V, +7V	Storage Temperature Range	-65°C to +150°C
$V_{DD}$ to DGND	0V, +7V	Operating Temperature Ranges	
AGND to DGND	-0.3V, $V_{DD}$	MAX160CPN, MX7574JN/KN/JCWN/KCWN	0°C to +70°C
Digital Inputs/Outputs (Pins 6-17)	DGND - 0.3V, $V_{DD}$ + 0.3V	MX7574AD/BD/AQ/BQ	-25°C to +85°C
Analog Inputs (Pins 2-4)	-20V, +20V	MAX160EPN	-40°C to +85°C
Power Dissipation (Any Package) to +70°C	670mW	MAX160MDN/MJN	-55°C to +125°C
Derate Above +70°C by	8.3mW/°C	MX7574SD/TD/SQ/TQ	-55°C to +125°C
		Lead Temperature (Soldering 10 seconds)	+300°C

Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions above those indicated in the operational sections of the specification is not implied. Exposure to absolute maximum ratings conditions for extended periods may affect the device reliability.

### **ELECTRICAL CHARACTERISTICS — MAX160, MX7574**

( $V_{DD} = +5V$ ,  $V_{REF} = -10V$ , Unipolar Configuration, Slow Memory Mode using External Clock  $f_{CLK} = 2.0MHz$  for MAX160 and 0.5MHz for MX7574 (Fig. 9),  $T_A = T_{MIN}$  to  $T_{MAX}$ , unless specified otherwise.)

**MAX160/MX7574**

### **ELECTRICAL CHARACTERISTICS — MAX160, MX7574 (continued)**

PARAMETER	SYMBOL	CONDITIONS	MIN.	TYP.	MAX.	UNITS
<b>LOGIC OUTPUTS</b>						
Logic Output High Voltage	$V_{OH}$	BUSY, DB0-DB7 $I_{SRC} = 200\mu A$	4.0			V
Logic Output Low Voltage	$V_{OL}$	$T_A = +25^\circ C$		0.4		V
		$T_A = T_{MIN} \text{ to } T_{MAX}$ MAX160 MX7574		0.4	0.8	
Floating State Leakage	$I_{LKG}$	DB0-DB7, $V_{OUT} = 0, V_{DD}$	$T_A = +25^\circ C$	1	10	$\mu A$
Floating State Capacitance (Note 5)		DB0-DB7	$T_A = T_{MIN} \text{ to } T_{MAX}$	5	7	pF
<b>POWER REQUIREMENTS</b>						
Power Supply Requirement	$V_{DD}$	+5V $\pm 5\%$ for specified performance	4.75	5.25		V
Power Supply Current	$I_{DD}$	$A_{IN} = 0V$ , ADC in reset condition	1	5		mA
Reference Current	$I_{REF}$	Conversion complete, before reset			$V_{REF}/5$	V/k $\Omega$

**Note 1:** Full scale error is measured after correcting for offset error. Max full-scale change from  $+25^\circ C$  to  $T_{MIN}$  or  $T_{MAX}$  is  $\pm 1$  LSB.

**Note 2:** Maximum offset change from  $+25^\circ C$  to  $T_{MIN}$  or  $T_{MAX}$  is  $\pm 10$  mV. Typical offset temperature coefficient is  $50\mu V/^\circ C$ .

**Note 3:**  $R_{BOFS}/R_{AIN}$  mismatch causes transfer function rotation about positive full scale. The effect is an offset and gain term when using the circuit of Figure 9b.

**Note 4:** Typical value, not guaranteed or subject to test.

**Note 5:** Guaranteed but not tested.

### ***Pin Description***

PIN	NAME	FUNCTION	PIN	NAME	FUNCTION
1	V <sub>DD</sub>	Power supply voltage, +5V.	11	DB2	Three-state data output, bit 2.
2	V <sub>REF</sub>	Reference Input, nominal -10V.	12	DB1	Three-state data output, bit 1.
3	B <sub>0FS</sub>	Bipolar Offset Input, +10V for bipolar mode, connect to A <sub>IN</sub> for unipolar mode.	13	DB0	Three-state data output, bit 0 (LSB).
4	A <sub>IN</sub>	Analog input, 0 to +10V for unipolar mode, -10V to +10V for bipolar mode.	14	BUSY	BUSY output, BUSY goes low at the start of a conversion and returns high when the conversion is complete.
5	AGND	Analog Ground.	15	RD	READ input, RD must be low to access data. See Digital Interface section.
6	DB7	Three-state data output, bit 7 (MSB).	16	CS	CHIP-SELECT input. Used for conversion control or device addressing. See Digital Interface section.
7	DB6	Three-state data output, bit 6.	17	CLK	External clock input/Internal clock frequency set input.
8	DB5	Three-state data output, bit 5.	18	DGND	Digital Ground.
9	DB4	Three-state data output, bit 4.			
10	DB3	Three-state data output, bit 3.			

### ***Detailed Description***

#### ***Converter Operation***

The MAX160/MX7574 uses the successive approximation technique to convert an unknown analog input to an 8 bit digital output code. The control logic provides easy interface to most microprocessors. Most applications require only passive clock components, a -10V reference, and a +5V power supply.

Figure 3 shows the MAX160/MX7574 functional diagram. When a start command is received from CS or RD (see Digital Interface Section), BUSY goes low indicating that the conversion is in progress. Successive bits, starting with the most significant bit (MSB), are applied to the input of a DAC. The comparator determines whether the addition of the bit causes the DAC output to be larger or smaller than the analog input, A<sub>IN</sub>. If the DAC output is greater than A<sub>IN</sub>, the trial bit is turned OFF, otherwise it is kept ON. Each successively smaller bit is tried and compared to A<sub>IN</sub> in this manner until the least significant bit (LSB) decision has been made.

When all bits have been tried, BUSY goes high, indicating that the conversion is complete and the successive approximation register contains a valid representation of the analog input. The data can then be read using the RD input (see Digital Interface Section).

#### ***DAC Circuit Details***

A thin film R-2R resistor network provides binarily weighted currents for each bit in the internal multi-

plying DAC (see Figure 4). N-channel MOS switches are used to steer current to either the summing junction or AGND depending on the DAC digital code. The A<sub>IN</sub> and B<sub>0FS</sub> input resistors also use series MOS switches (always ON) that match the DAC switches to maintain gain temperature tracking.

## ***μP Compatible 8 Bit A/D Converter***

### ***Digital Interface***

The MAX160/MX7574 has three interface modes which are determined by the timing of the CS and RD inputs.

#### ***Static RAM Interface Mode***

Table 5 and Figure 5 show the truth table and timing requirements for interfacing the MAX160/MX7574 as a static RAM.

A conversion is started by executing a memory WRITE instruction to the MAX160/MX7574 address. Once a conversion is in progress, subsequent WRITE operations have no effect. Data is read by executing a memory READ operation to the A/D's address.

BUSY must be high before a READ is attempted. In other words, the elapsed time between WRITE and READ must be greater than the conversion time. Once BUSY is HIGH (end of conversion) the data READ can be performed. The data readout is destructive, since the MAX160/MX7574 is internally reset when RD goes high. Note that CS remaining LOW longer than the hold time ( $t_{RHCS}$ ) will initiate a new conversion.

#### ***ROM Interface Mode***

Table 6 and Figure 6 show the truth table and timing requirements for interfacing the MAX160/MX7574 as Read Only Memory.

In this mode the CS input is not used and is held low. The RD input is derived from the decoded device address. A data READ is initiated by executing a memory READ instruction to the MAX160/MX7574 address location. A conversion automatically starts when RD returns HIGH. Similar to the RAM mode, attempting a READ before BUSY goes HIGH will result in incorrect data being read.

The advantage of the ROM mode is its simplicity. The major disadvantage is that the data obtained is poorly defined in time since the conversion is performed at the end of a previous READ operation. This problem can be overcome by performing two READ operations back to back and only using the data from the second read.

#### ***Slow-Memory Interface Mode***

Table 7 and Figure 7 show the truth table and timing requirements for interfacing the MAX160/MX7574 as slow memory. This mode is intended for processors that can be forced into a WAIT state for periods as long as the MAX160/MX7574 conversion time.

In this mode CS and RD are tied together. The decoded device address is used to drive CS/RD.

The BUSY output is connected to the processor's READY input. A conversion is initiated by executing a memory READ to the MAX160/MX7574 address. BUSY then goes LOW and forces the processor into a WAIT state. At the end of the conversion, BUSY returns high and the data is available at the data outputs.

The major advantage of the slow memory mode is that it allows the processor to start and end a conversion and read the result with a single READ instruction.

Do not attempt a memory WRITE in this mode, since a three-state bus conflict will arise.

### ***Interface Application Hints***

#### ***Timing and Control***

Failure to observe the timing restrictions of Figures 5-7 may cause the MAX160/MX7574 to change interface modes. For example, in the RAM mode, if CS is held low for too long, the converter moves into the ROM mode since a new conversion starts.

#### ***Logic Deglitching In μP Applications***

Unspecified states in the address bus can cause glitches at the MAX160/MX7574 CS or RD inputs. Such glitches can cause undesired conversion starts, resets or data reads. The best method for avoiding these problems is to gate the address decode with WR or RD when in the RAM or ROM modes. In the slow memory mode use latched address inputs.

#### ***Initialization After Power-Up***

To initialize the MAX160/MX7574 at power-up, perform a memory READ to its address location and ignore the data.

### ***Clock***

#### ***Internal Oscillator***

The MAX160/MX7574 has an internal asynchronous clock oscillator which starts when a convert command is received and stops at the end of a conversion.

The oscillator requires an external resistor and capacitor connected as shown in Figure 8. The internal oscillator has good initial accuracy and stability over temperature and supply voltage. See Typical Operating Characteristics for typical conversion times versus RCLK with CCLK set at 100pF.

To prevent false triggering of the internal clock, RCLK and CCLK must be placed close to the CLK pin and coupling from the CS and RD inputs must be minimized.

Figure 9. External Clock Operation (Static RAM and Slow Memory Mode)

### **Operation With External Clock**

For applications where synchronous operation is required or the conversion time must be accurately controlled, an external clock can be used.

Figure 9 shows how an external clock is connected. The BUSY output is connected to the three-state enable input of a 74125 buffer. A 500kHz clock provides a conversion time of 15μs.

The external clock should be used only in the static-RAM or slow-memory modes and *not* in the ROM mode. Timing constraints for the external clock operation are as follows:

#### **STATIC RAM MODE**

1. When initiating a conversion, CS should go low on a positive clock edge to provide optimum settling time for the MSB.
2. A data READ can be performed at any time after BUSY = HIGH.

#### **SLOW MEMORY MODE**

1. When starting a conversion, CS and RD should go low on a positive clock edge to provide optimum settling time for the MSB.

### **Analog Considerations**

#### **Application Hints**

##### **Input Loading at $V_{REF}$ , $A_{IN}$ , and $B_{OFs}$**

To prevent input loading effects due to the finite input resistance of these pins, low impedance driving sources must be used (i.e. op-amp buffers, or low output impedance references).

##### **Ratiometric Operation**

Ratiometric operation is inherent for the multiplying DAC scheme used on the MAX160/MX7574. However, the user must recognize that comparator limitations such as offset voltage, input noise and gain degrade the transfer function at reference voltages less than -10V.

##### **Offset Correction**

Offset error in the transfer function can be trimmed by offsetting the buffer that drives the  $A_{IN}$  input. This can be achieved either by summing a cancellation current into the amplifier's summing junction, or by tapping a voltage divider which sits between  $V_{DD}$  and  $V_{REF}$  and applying the tap voltage to the amplifier's non-inverting input. An example of the latter method can be seen in Figure 12.

##### **Analog and Digital Ground**

It is recommended that the AGND and DGND pins be connected locally to prevent noise injection into the A/D converter. In systems where the AGND-DGND connection is not local, clamp diodes should be connected between AGND and DGND to keep the two ground busses within one diode drop of each other.

##### **Unipolar Binary Operation**

Figures 10 shows the analog circuit connections and nominal transfer characteristic for unipolar operation. Calibration is as follows:

##### **Offset**

If offset trimming is required, it must be done in the signal conditioning circuitry used to drive the  $A_{IN}$  input in Figure 10. See also the offset trim example shown in Figure 12.

1. Apply -39.1mV (1 LSB) to the input of the buffer amplifier used to drive R1 (i.e. +39.1 mV at R1).
2. Adjust the offset potentiometer until DB7-DB1 are LOW and DB0 flickers.

##### **Gain (Full Scale)**

Offset adjustment must be performed prior to gain adjustment. To trim gain:

1. Apply -9.961V to the input of the buffer that drives R1 (i.e. +9.961V at R1).
2. Adjust trimpot R2 until DB7-DB1 are HIGH and DB0 flickers.

### ***Bipolar (Offset Binary) Operation***

Figure 11 illustrates the analog circuitry and transfer function for bipolar operation. The output coding is offset binary. Offset correction can be performed at the buffer amplifier used to drive the signal input terminals of the MAX160/MX7574. See Figure 12 for an example of how offset trimming can be performed. Calibration is as follows:

1. Adjust R6 and R7 for minimum resistance across the potentiometers.
2. Apply +10.000V to the buffer amplifier used to drive the signal input (i.e. -10.000V at R6). Then trim R6 or R7 (whichever is required) until DB7-DB1 are LOW

and DB0 flickers.

3. Apply 0V to the buffer amplifier used to drive the signal input terminals. Then trim the offset circuit of the buffer amplifier until the ADC output flickers between 0111111 and 1000000.
4. Apply +10.000V to the input of the buffer amplifier (i.e. -10.000V as applied to R6). Then trim R2 until DB7-DB1 are LOW and DB0 flickers.
5. Apply -9.922V to the input of the buffer amplifier (i.e. +9.922V at the input side of R6). If the ADC output code is not 1111110 ± 1 bit, repeat the calibration procedure.

Figure 10. Unipolar (0V to +10V) Operation and Nominal Transfer Characteristic (Output Code is Straight Binary)

Figure 11. Bipolar (-10V to +10V) Operation and Nominal Transfer Characteristic Around Major Carry (Output Code is Offset Binary)

### ***Bipolar (Complementary Offset Binary) Operation***

Figure 12 shows the analog connections for offset binary operation. The typical transfer characteristic is also shown. In this bipolar mode, the input signal (-10 to +10V) is conditioned and the A/D basically operates in unipolar mode (0 to +10V). Calibration is as follows (offset adjusted before gain):

Figure 12. Bipolar (-10V to +10V) Operation and Nominal Transfer Characteristic Around Major Carry (Output Code is Complementary Offset Binary)
