## APPLICATIONS

- Analog multiplexing and demultiplexing
- Digital multiplexing and demultiplexing
- Signal gating

## GENERAL DESCRIPTION

Each multiplexer/demultiplexer contains two bidirectional analog switches, each with one side connected to an independent input/output ( $n Y_{0}$ and $n Y_{1}$ ) and the other side connected to a common input/output ( nZ ).
With $\tilde{E}_{1}$ LOW and $E_{2} \mathrm{HIGH}$, one of the two switches is selected (low impedance ON -state) by $\mathrm{S}_{\uparrow}$ to $\mathrm{S}_{3}$.
The data at the select inputs may be latched by using the active LOW latch enable input ( $\overline{\mathrm{LE}}$ ). When $\overline{\mathrm{LE}}$ is HIGH, the latch is transparent. When either of the two enable inputs, $\bar{E}_{1}$ (active LOW) and $E_{2}$ (active HIGH), is inactive, all analog switches are turned off.
$V_{C C}$ and GND are the supply voltage pins for the digital control inputs ( $S_{1}$ to $S_{3}$. $\overline{L E}, \bar{E}_{1}$ and $E_{2}$ ). The $V_{C C}$ to GND ranges are 2.0 to 10.0 V for HC and 4.5 to 5.5 V for HCT. The analog inputs/outputs ( $n Y_{0}$ and $n Y_{1}$, and $n Z$ ) can swing between $V_{C C}$ as a positive limit and $V_{E E}$ as a negative limit. $V_{C C}-V_{E E}$ may not exceed 10.0 V .
For operation as a digital multiplexer/demultiplexer, $V_{E E}$ is connected to GND (typically ground).

## Note to ratings

To avoid drawing $V_{C C}$ current out of terminals $n Z$, when switch current flows in terminals $n Y_{n}$, the voltage drop across the bidirectional switch must not exceed 0.4 V . If the switch current flows into terminals $n Z$, no $V_{C C}$ current will flow out of terminals $n Y_{n}$. In this case there is no limit for the voltage drop across the switch, but the voltages at $n Y_{n}$ and $n Z$ may not exceed $V_{C C}$ or $V_{E E}$.

## Notes to DC characteristics

1. At supply voltages ( $\mathrm{V}_{\mathrm{CC}}-\mathrm{V}_{\mathrm{EE}}$ ) approaching 2.0 V the analog switch ON -resistance becomes extremely non-linear. There it is recommended that these devices be used to transmit digital signals only, when using these supply voltages.
2. For test circuit measuring $\mathrm{R}_{\mathrm{ON}}$ see Fig. 8.

## Notes to AC characteristics

General note
$V_{i s}$ is the input voltage at an $n Y_{n}$ or $n Z$ terminal, whichever is assigned as an input.
$V_{\text {os }}$ is the output voltage at an $n Y_{n}$ or $n Z$ terminal, whichever is assigned as an output.
Notes

1. Adjust input voltage $V_{\text {is }}$ to 0 dBm level ( $0 \mathrm{dBm}=1 \mathrm{~mW}$ into $600 \Omega$ ).
2. Adjust input voltage $V_{\text {is }}$ to 0 dBm level at $V_{\mathrm{os}}$ for $1 \mathrm{MHz}(0 \mathrm{dBm}=1 \mathrm{~mW}$ into $50 \Omega)$.

Note to Figs 12 and 13
Test conditions:
$V_{C C}=4.5 \mathrm{~V} ; \mathrm{GND}=0 \mathrm{~V} ; V_{E E}=-4.5 \mathrm{~V}$;
$R_{L}=50 \Omega ; R_{\text {source }}=1 \mathrm{k} \Omega$.

The crosstalk is defined as follows (oscilloscope output):

$$

$$

## Conditions

| TEST | SWITCH | $V_{\text {is }}$ |

| tPZH | $V_{E E}$ | $V_{C C}$ |
| t $_{\text {PZL }}$ | $V_{C C}$ | $V_{E E}$ |

Definitions for Figs 21 and 22:
$\mathrm{C}_{\mathrm{L}}=$ load capacitance including jig and probe capacitance
(see AC CHARACTERISTICS for values).
$\mathrm{R}_{\mathbf{T}}=$ termination resistance should be equal to the output impedance $\mathrm{Z}_{\mathrm{O}}$ of the pulse generator.
$\mathrm{t}_{\mathrm{r}}=\mathrm{t}_{\mathrm{f}}=6 \mathrm{~ns}$; when measuring $f_{\text {max }}$, there is no constraint on $t_{r}, t_{f}$ with $50 \%$ duty factor.
