## DS1609 Dual Port RAM

T-46-23-05

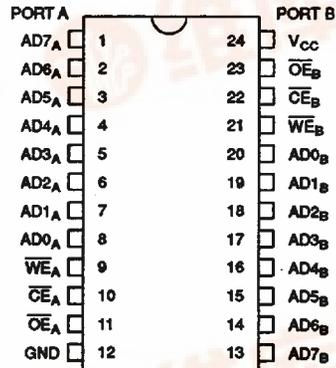

### FEATURES

- Totally asynchronous 256 byte dual port memory
- Multiplexed address and data bus keeps pin count low
- Dual port memory cell allows random access with minimum arbitration
- Each port has standard independent RAM control signals
- Fast access time
- Low power CMOS design
- 24 pin DIP or 24 pin SOIC surface mount package
- Both CMOS and TTL compatible
- Reduced performance operation down to 2.5 volts
- Operating temperature of  $-40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$
- Standby current of 100 nA @  $25^{\circ}\text{C}$  makes the device ideal for battery backup or battery operate applications.

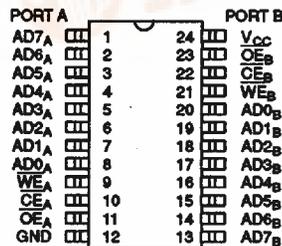

### DESCRIPTION

The DS1609 is a random access 256 byte dual port memory designed to connect two asynchronous address/data buses together with a common memory element. Both ports have unrestricted access to all 256 bytes of memory and with modest system discipline no arbitration is required. Each port is controlled by three

### PIN ASSIGNMENT

DS1609  
24 PIN DIP (600 mil)  
See Mech. Drawing - Sect. 16, Pg. 4

DS1609S  
24 PIN SOIC (300 mil)  
See Mech. Drawing - Sect. 16, Pg. 6

### PIN DESCRIPTION

V <sub>CC</sub>	- +5 volt supply
GND	- Ground
AD0-AD7	- Port address/data
$\overline{\text{CE}}$	- Port enable
$\overline{\text{OE}}$	- Output enable
$\overline{\text{WE}}$	- Write enable

control signals: output enable, write enable, and port enable. The device is packaged in plastic 24 pin DIP and 24 pin SOIC. Output enable access times of 35 ns are available when operating at 5 volts. Reduced performance operation at reduced voltage can be achieved down to 2.5 volts.

**OPERATION – READ CYCLE**

The main elements of the dual port RAM are shown in Figure 1.

A read cycle to either port begins by placing an address on the multiplexed bus pins AD0 - AD7. The port enable control ( $\overline{CE}$ ) is then transitioned low. This control signal causes address to be latched internally. Addresses can be removed from the bus provided address hold time is met. Next, the output enable control ( $\overline{OE}$ ) is transitioned low, which begins the data access portion of the read cycle. With both  $\overline{CE}$  and  $\overline{OE}$  active low, data will appear valid after the output enable access time  $t_{OEA}$ . Data will remain valid as long as both port enable and output enable remains low. A read cycle is terminated with the first occurring rising edge of either  $\overline{CE}$  or  $\overline{OE}$ . The address/data bus will return to a high impedance state after time  $t_{CEZ}$  or  $t_{OEZ}$  as referenced to the first occurring rising edge.  $\overline{WE}$  must remain high during read cycles.

**OPERATION – WRITE CYCLE**

A write cycle to either port begins by placing an address on the multiplexed bus pins AD0 - AD7. The port enable control ( $\overline{CE}$ ) is then transitioned low. This control signal causes address to be latched internally. As with a read cycle, the address can be removed from the bus provided address hold time is met. Next the write enable control signal ( $\overline{WE}$ ) is transitioned low which begins the write data portion of the write cycle. With both  $\overline{CE}$  and  $\overline{WE}$  active low the data to be written to the selected memory location is placed on the multiplexed bus. Provided that data setup ( $t_{PS}$ ) and data hold ( $t_{PH}$ ) times are met, data is written into the memory and the write cycle is terminated on the first occurring rising edge of either  $\overline{CE}$  or  $\overline{WE}$ . Data can be removed from the bus as soon

as the write cycle is terminated.  $\overline{OE}$  must remain high during write cycles.

T-46-23-05

**ARBITRATION**

The DS1609 dual port RAM has a special cell design that allows for simultaneous accesses from two ports (see Figure 2). Because of this cell design, no arbitration is required for read cycles occurring at the same instant. However, an argument for arbitration can be made for reading and writing the cell at the exact same instant or a write from both ports at the same instant. If a write cycle occurs while a read cycle is in progress, the read cycle will likely recover either the old data or new data and not some combination of both. However, the write cycle will update the memory with correct data. Simultaneous write cycles to the same memory location pose the additional concern that the cell may be in contention causing a metastable state. Depending on the timing of the write cycles of port A and port B, the memory location could be left containing the data written from port A or the data from port B or some combination thereof. However, both concerns expressed above can be eliminated by disciplined system software design. A simple way to assure that read/write arbitration doesn't occur is to perform redundant read cycles. Write/write arbitration needs can be avoided by assigning groups of addresses for write operation to one port only. Groups of data can be assigned check sum bytes which would guarantee correct transmission. A software arbitration system using a "mail box" to pass status information can also be employed. Each port could be assigned a unique byte for writing status information which the other port would read. The status information could tell the reading port if any activity is in progress and indicate when activity is going to occur.

## DUAL PORT RAM TIMING: READ CYCLE

DURING READ CYCLE  $\overline{WE} = V_{IH}$ 

T-46-23-05

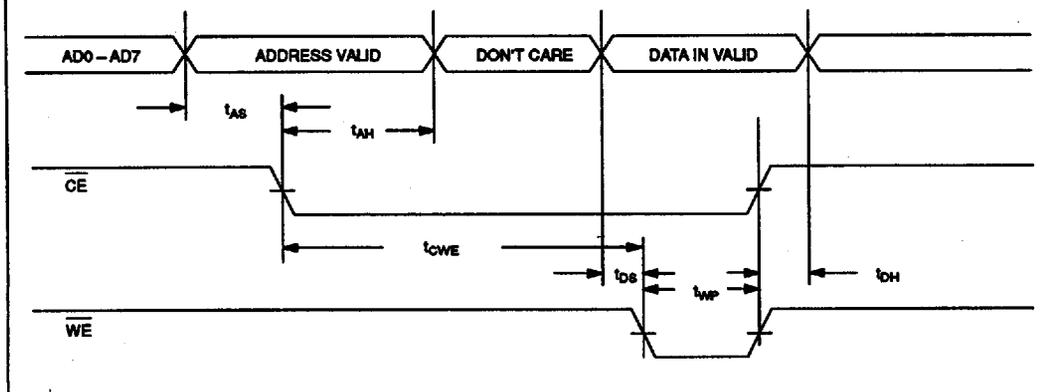

3

## NOTES

1. During read cycle the address must be off the bus prior to  $t_{OEA}$  minimum to avoid bus contention.
2. Read cycles are terminated by the first occurring rising edge of  $\overline{OE}$  or  $\overline{CE}$ .

## DUAL PORT RAM TIMING: WRITE CYCLE

DURING WRITE CYCLE  $\overline{OE} = V_{IH}$ 

## NOTE

1. Write cycles are terminated by the first occurring edge of  $\overline{WE}$  or  $\overline{CE}$ .

DALLAS SEMICONDUCTOR CORP 50E D ■ 2614130 0004600 0 ■ DAL  
**NOTES**

1. All Voltages are referenced to ground.
2. All pins other than  $\overline{CE}$ ,  $\overline{WE}$ ,  $\overline{OE}$ ,  $V_{CC}$  and ground are continuously driven by a feedback latch in order to hold the inputs at one power supply rail or the other when an input is tristated. The minimum driving impedance presented to any pin is  $50K\Omega$ . If a pin is at a logic low level, this impedance will be pulling the pin to ground. If a pin is at a logic high level, this impedance will be pulling the pin to  $V_{CC}$ .
3. Standby current is measured with outputs open circuited.
4.  $I_{CCS1}$  is measured with all pins within  $0.3V$  of  $V_{CC}$  or GND and with  $\overline{CE}$  at a logic high or logic low level.
5.  $I_{CCS2}$  is measured with all pins within  $0.3V$  of  $V_{CC}$  or ground and with  $\overline{CE}$  within  $0.3V$  of  $V_{CC}$ .
6.  $I_{CCS3}$  is measured with all pins at  $V_{CC}$  or ground potential and with  $\overline{CE} = V_{CC}$ . Note that if a pin is floating, the internal feedback latches will pull all the pins to one power supply rail or the other.
7. Active current is measured with outputs open circuited, and inputs swinging full supply levels with one port reading and one port writing at  $100$  ns cycle time. Active currents are a DC average with respect to the number of 0's and 1's being read or written.
8. Logic one voltages are specified at a source current of  $1$  mA.
9. Logic zero voltages are specified at a sink current of  $4$  mA.
10. Measured with a load as shown in Figure 3.
11.  $t_{yp}$  is defined as the time from  $\overline{WE}$  going low to the first of the rising edges of  $\overline{WE}$  and  $\overline{CE}$ .
12. Recovery time is the amount of time control signals must remain high between successive cycles.
13. Typical values are at  $25^{\circ}C$ .
