

ADS805

## Speed<sup>PLUS</sup>™ 12-Bit, 20MHz Sampling ANALOG-TO-DIGITAL CONVERTER

### FEATURES

- HIGH SFDR: 74dB at 9.8MHz  $f_{IN}$
- HIGH SNR: 68dB
- LOW POWER: 300mW
- LOW DLE: 0.25LSB
- SMALL 28-LEAD SSOP AND SOIC PACKAGES

- FLEXIBLE INPUT RANGE
- OVER-RANGE INDICATOR

### APPLICATIONS

- STUDIO CAMERAS
- IF AND BASEBAND DIGITIZATION
- COPIERS
- TEST INSTRUMENTATION

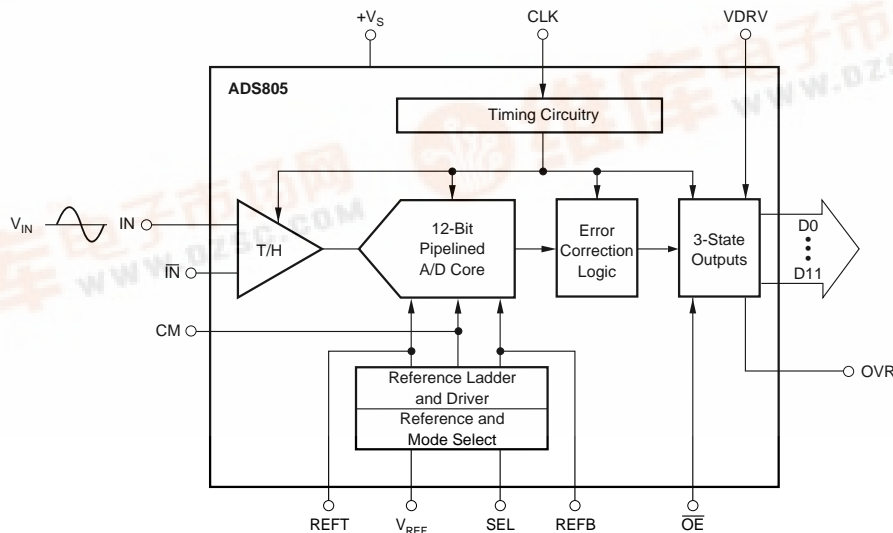

### DESCRIPTION

The ADS805 is a 20MHz, high dynamic range, 12-bit pipelined analog-to-digital converter. This converter includes a high-bandwidth track/hold that gives excellent spurious performance up to and beyond the Nyquist rate. This high-bandwidth, linear track/hold minimizes harmonics and has low jitter, leading to excellent SNR performance. The ADS805 is also pin-compatible with the 10MHz ADS804 and the 5MHz ADS803.

The ADS805 provides an internal reference or an external reference can be used. ADS805 can be programmed for a 2Vp-p input range which is the easiest to drive with a single op amp and provides the best spurious performance. Alternatively, the 5Vp-p input range can be used for the lowest input-referred noise of 0.09 LSBs rms giving

superior imaging performance. There is also the capability to set the input range between 2Vp-p and 5Vp-p, either single-ended or differential. The ADS805 also provides an overrange flag that indicates when the input signal has exceeded the converter's full scale range. This flag can also be used to reduce the gain of the front end signal conditioning circuitry.

The ADS805 employs digital error techniques to provide excellent differential linearity for demanding imaging applications. Its low distortion and high SNR give the extra margin needed for communications, medical imaging, video and test instrumentation applications. The ADS805 is available in 28-lead SSOP and SOIC packages.

# SPECIFICATIONS

At  $T_A$  = full specified temperature range,  $V_S$  = +5V, specified input range = 1.5V to 3.5V, single-ended input and sampling rate = 20MHz, unless otherwise specified.

Junction Temperature .....	+150°C
Storage Temperature .....	+150°C

## ELECTROSTATIC DISCHARGE SENSITIVITY

This integrated circuit can be damaged by ESD. Burr-Brown recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

# APPLICATION INFORMATION

## DRIVING THE ANALOG INPUT

The ADS805 allows its analog inputs to be driven either single-ended or differentially. The focus of the following discussion is on the single-ended configuration. Typically, its implementation is easier to achieve and the rated specifications for the ADS805 are characterized using the single-ended mode of operation.

## AC-COUPLED INPUT CONFIGURATION

Given in Figure 1 is the circuit example of the most common interface configuration for the ADS805. With the  $V_{REF}$  pin connected to the SEL pin, the full-scale input range is defined to be 2Vp-p. This signal is ac-coupled in single-ended form to the ADS805 using the low distortion voltage-feedback amplifier OPA642. As is generally necessary for single-supply components, operating the ADS805 with a full-scale input signal swing requires a level-shift of the amplifier's zero centered analog signal to comply with the A/D converter's input range requirements. Using a DC blocking capacitor between the output of the driving amplifier and the converter's input, a simple level-shifting scheme can be implemented. In this configuration, the top and bottom references (REFT, REFB) provide an output voltage of +3V and +2V, respectively. Here, two resistor pairs ( $2 \times 2k\Omega$ ) are used to create a common-mode voltage of approximately +2.5V to bias the inputs of the ADS805 (IN,  $\overline{IN}$ ) to the required DC voltage.

An advantage of ac-coupling is that the driving amplifier still operates with a ground-based signal swing. This will keep the distortion performance at its optimum since the signal swing stays within the linear region of the op amp and sufficient headroom to the supply rails can be maintained. Consider using the inverting gain configuration to eliminate CMR induced errors of the amplifier. The addition of a small series resistor ( $R_S$ ) between the output of the op amp and the

input of the ADS805 will be beneficial in almost all interface configurations. This will decouple the op amp's output from the capacitive load and avoid gain peaking, which can result in increased noise. For best spurious and distortion performance, the resistor value should be kept below 100 $\Omega$ . Furthermore, the series resistor, together with the 100pF capacitor, establish a passive low-pass filter, limiting the bandwidth for the wideband noise, thus help improving the signal-to-noise performance.

## DC-COUPLED WITHOUT LEVEL SHIFT

In some applications the analog input signal may already be biased at a level which complies with the selected input range and reference level of the ADS805. In this case, it is only necessary to provide an adequately low source impedance to the selected input, IN or  $\overline{IN}$ . Always consider wideband op amps since their output impedance will stay low over a wide range of frequencies.

## DC-COUPLED WITH LEVEL SHIFT

Several applications may require that the bandwidth of the signal path includes DC, in which case the signal has to be DC-coupled to the A/D converter. In order to accomplish this, the interface circuit has to provide a DC-level shift. The circuit shown in Figure 2 utilizes the single-supply, current feedback op amp OPA681 (A1), to sum the ground centered input signal with a required DC offset. The ADS805 typically operates with a +2.5V common-mode voltage, which is established with resistors  $R_3$  and  $R_4$  and connected to the  $\overline{IN}$  input of the converter. Amplifier A1 operates in inverting configuration. Here, resistors  $R_1$  and  $R_2$  set the DC-bias level for A1. Because of the op amp's noise gain of +2V/V, assuming  $R_F = R_{IN}$ , the DC offset voltage applied to its non-inverting input has to be divided down to +1.25V, resulting in a DC output voltage of +2.5V. DC voltage differences between the IN and  $\overline{IN}$  inputs of the ADS805 effectively will produce an offset, which can be corrected for by adjusting

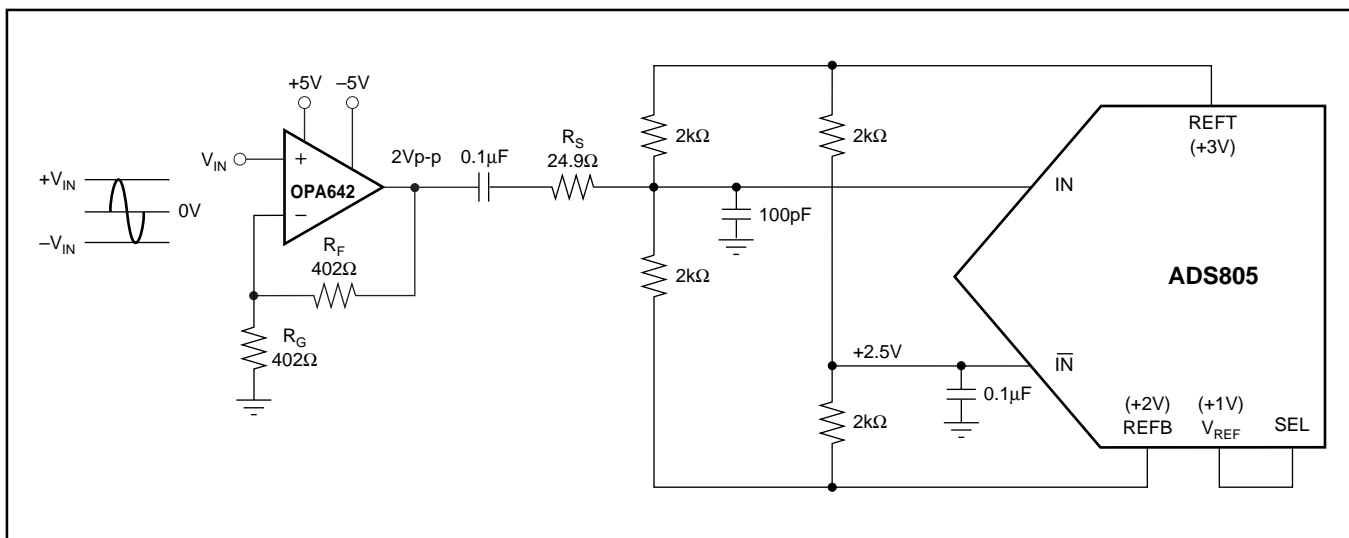

FIGURE 1. AC-Coupled Input Configuration for 2Vp-p Input Swing and Common-Mode Voltage at +2.5V Derived from Internal Top and Bottom Reference.

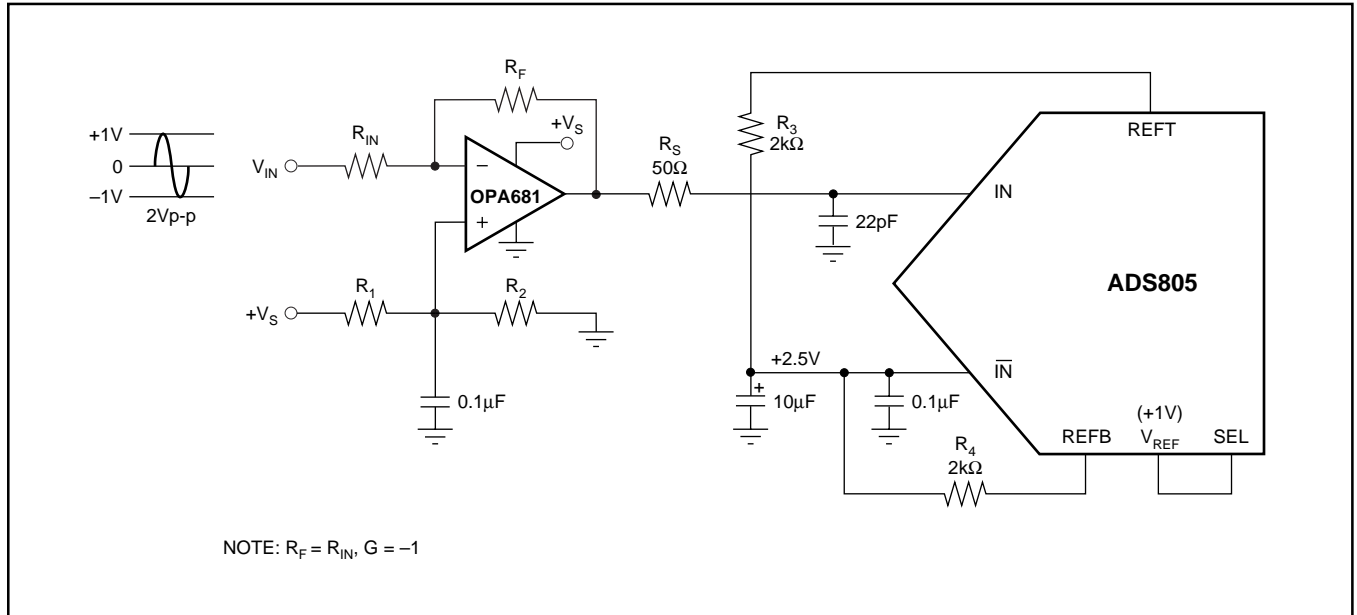

FIGURE 2. DC-Coupled, Single-Ended Input Configuration with DC-level Shift.

the values of resistors  $R_1$  and  $R_2$ . The bias current of the op amp may also result in an undesired offset. The selection criteria for an appropriate op amp should include the input bias current, output voltage swing, distortion and noise specification. Note that in this example the overall signal phase is inverted. To re-establish the original signal polarity it is always possible to interchange the IN and  $\overline{\text{IN}}$  connections.

### SINGLE-ENDED-TO-DIFFERENTIAL CONFIGURATION (TRANSFORMER COUPLED)

In order to select the best suited interface circuit for the ADS805, the performance requirements must be known. If an ac-coupled input is needed for a particular application, the next step is to determine the method of applying the signal; either single-ended or differentially. The differential input configuration may provide a noticeable advantage of achieving good SFDR performance based on the fact that in the differential mode the signal swing can be reduced to half of the swing required for single-ended drive. Secondly, by driving the ADS805 differentially, the even-order harmonics will be reduced. Figure 3 shows the schematic for the suggested transformer coupled interface circuit. The resistor across the secondary side ( $R_T$ ) should be set to get an input impedance match (e.g.,  $R_T = n^2 \cdot R_G$ ).

One application example that will benefit from the differential input configuration is the digitization of IF signals. The wide track-and-hold input bandwidth makes the ADS805 well suited for IF down conversion in both narrow and wideband applications. The ADS805 maintains excellent dynamic performance in multiple Nyquist regions covering a variety of IF frequencies (see Typical Performance Curves). Using the ADS805 for direct IF conversion eliminates the need of an analog mixer along with subsequent functions like amplifiers and filters thus reducing system cost and complexity.

FIGURE 3. Transformer Coupled Input.

### REFERENCE OPERATION

Integrated into the ADS805 is a bandgap reference circuit including logic that provides either a +1V or +2.5V reference output, by simply selecting the corresponding pin-strap configuration. Different reference voltages can be generated by the use of two external resistors, which will set a different gain for the internal reference buffer. For more design flexibility, the internal reference can be shut off and an external reference voltage used. Table I provides an overview of the possible reference options and pin configurations.

MODE	INPUT FULL-SCALE RANGE	REQUIRED $V_{REF}$	CONNECT	TO
Internal	2Vp-p	+1V	SEL	$V_{REF}$
Internal	5Vp-p	+2.5V	SEL	GND
Internal	$2V \leq \text{FSR} < 5V$ $\text{FSR} = 2 \times V_{REF}$	$1V < V_{REF} < 2.5V$ $V_{REF} = 1 + (R_1/R_2)$	$R_1$ $R_2$	$V_{REF}$ and SEL SEL and Gnd
External	$1V < \text{FSR} < 5V$	$0.5V < V_{REF} < 2.5V$	SEL $V_{REF}$	+ $V_S$ Ext. $V_{REF}$

TABLE I. Selected Reference Configuration Examples.

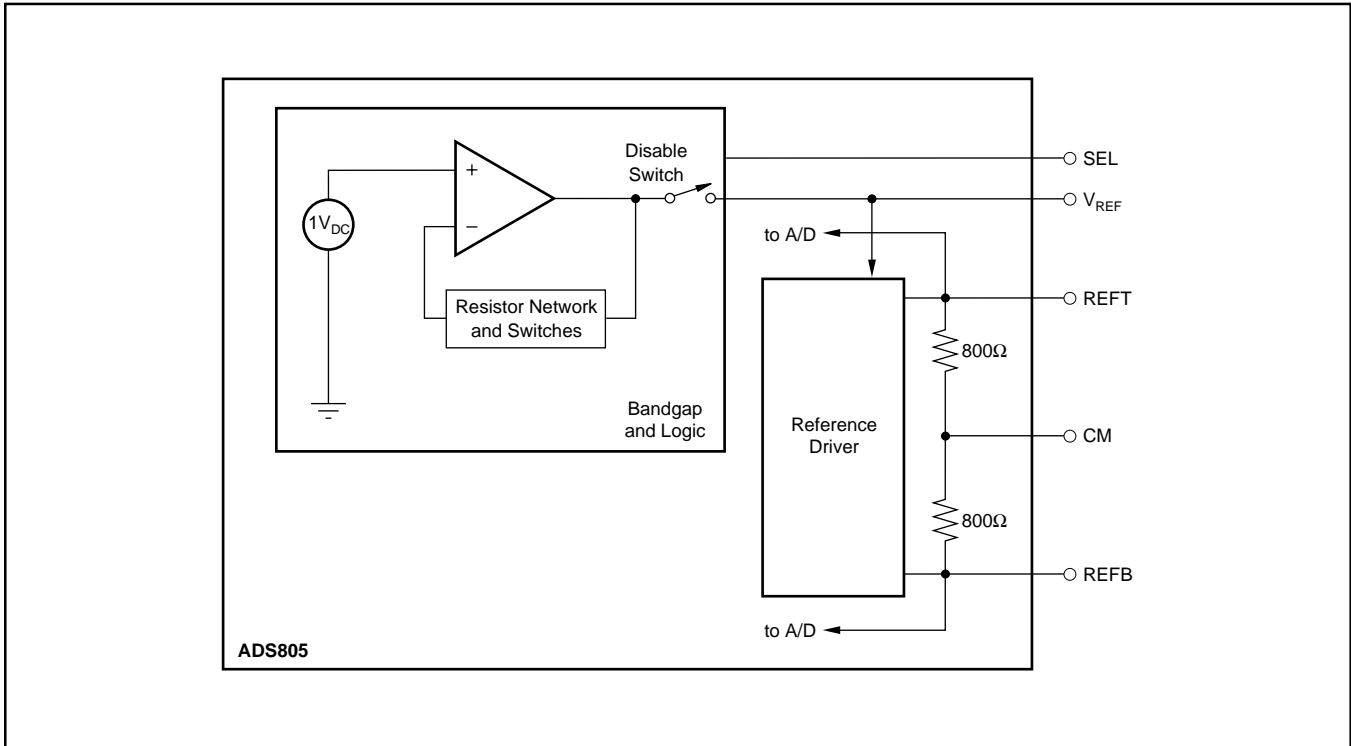

FIGURE 4. Equivalent Reference Circuit.

A simple model of the internal reference circuit is shown in Figure 4. The internal blocks are a 1V-bandgap voltage reference, buffer, the resistive reference ladder and the drivers for the top and bottom reference which supply the necessary current to the internal nodes. As shown, the output of the buffer appears at the  $V_{REF}$  pin. The full-scale input span of the ADS805 is determined by the voltage at  $V_{REF}$ , according to the Equation 1:

$$\text{Full-Scale Input Span} = 2 \times V_{REF} \quad (1)$$

Note that the current drive capability of this amplifier is limited to approximately 1mA and should not be used to drive low loads. The programmable reference circuit is controlled by the voltage applied to the select pin (SEL). Refer to Table I for an overview.

The top reference (REFT) and the bottom reference (REFB) are brought out mainly for external bypassing. For proper

operation with all reference configurations, it is necessary to provide solid bypassing to the reference pins in order to keep the clock feedthrough to a minimum. Figure 5 shows the recommended decoupling network.

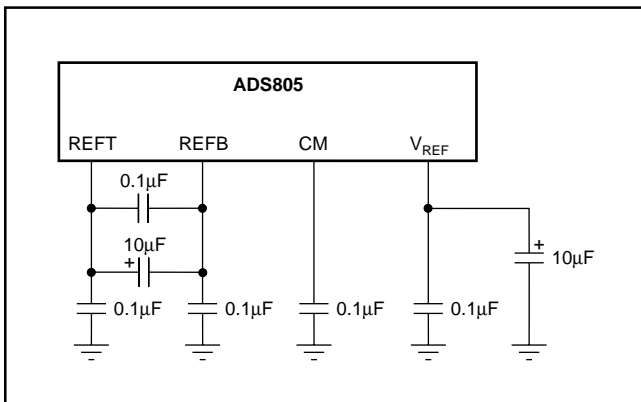

FIGURE 5. Recommended Reference Bypassing Scheme.

FIGURE 6. Alternative Circuit to Generate Common-Mode Voltage.

In addition, the common-mode voltage (CMV) may be used as a reference level to provide the appropriate offset for the driving circuitry. However, care must be taken not to appreciably load this node, which is not buffered and has a high impedance. An alternate method of generating a common-mode voltage is given in Figure 6. Here, two external precision resistors (tolerance 1% or better) are located between the top and bottom reference pins. The common-mode level will appear at the midpoint. The output buffers of the top and bottom reference are designed to supply approximately 2mA of output current.

## SELECTING THE INPUT RANGE AND REFERENCE

Figures 7 through 9 show a selection of circuits for the most common input ranges when using the internal reference of the ADS805. All examples are for single-ended input and operate with a nominal common-mode voltage of +2.5V.

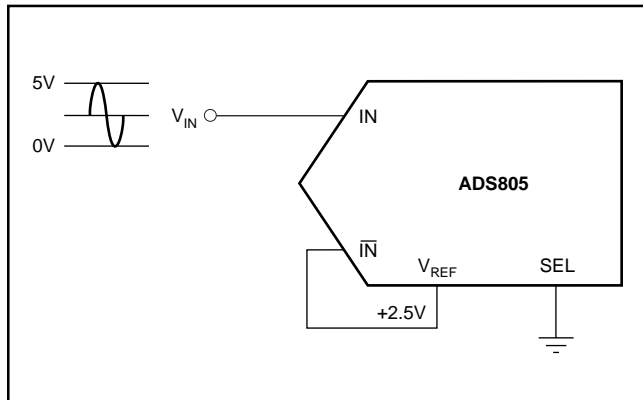

FIGURE 7. Internal Reference with 0V to 5V Input Range.

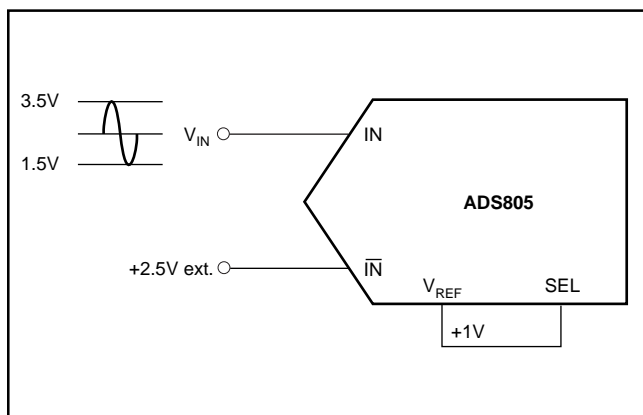

FIGURE 8. Internal Reference with 1.5V to 3.5V Input Range.

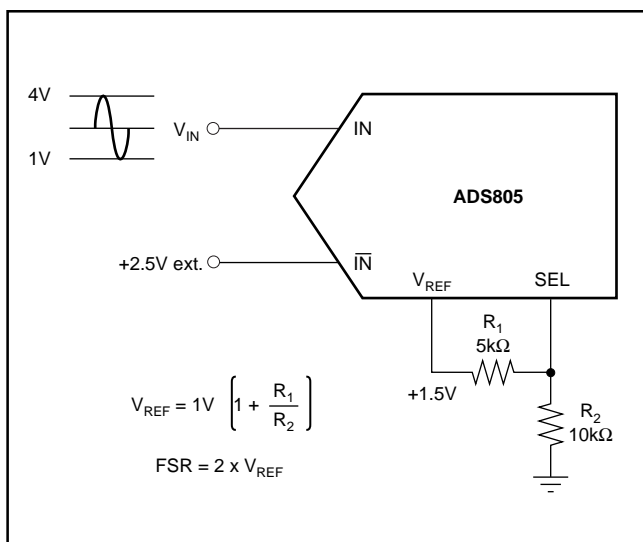

FIGURE 9. Internal Reference with 1V to 4V Input Range.

## EXTERNAL REFERENCE OPERATION

Depending on the application requirements, it might be advantageous to operate the ADS805 with an external reference. This may improve the DC accuracy if the external reference circuitry is superior in its drift and accuracy. To use the ADS805 with an external reference, the user must disable the internal reference (see Figure 10). By connecting the SEL pin to +V<sub>S</sub>, the internal logic will shut down the internal reference. At the same time, the output of the internal reference buffer is disconnected from the V<sub>REF</sub> pin, which now must be driven with the external reference. Note that a similar bypassing scheme should be maintained as described for the internal reference operation.

FIGURE 10. External Reference, Input Range 0.5V to 4.5V (4Vp-p), with +2.5V Common-Mode Voltage.

## DIGITAL INPUTS AND OUTPUTS

### Over Range (OVR)

One feature of the ADS805 is its 'Over Range' digital output (OVR). This pin can be used to monitor any out-of-range condition, which occurs every time the applied analog input voltage exceeds the input range (set by V<sub>REF</sub>). The OVR output is LOW when the input voltage is within the defined input range. It becomes HIGH when the input voltage is beyond the input range. This is the case when the input voltage is either below the bottom reference voltage or above the top reference voltage. OVR will remain active until the analog input returns to its normal signal range and another conversion is completed. Using the MSB and its complement in conjunction with OVR, a simple decode logic can be built that detects the overrange and underrange conditions, (see Figure 11). It should be noted that OVR is a digital output which is updated along with the bit information corresponding to the particular sampling incidence of the analog signal. Therefore, the OVR data is subject to the same pipeline delay (latency) as the digital data.

FIGURE 11. External Logic for Decoding Underrange and Overrange Condition.

### CLOCK INPUT REQUIREMENTS

Clock jitter is critical to the SNR performance of high speed, high resolution analog-to-digital converters. It leads to aperture jitter ( $t_A$ ) which adds noise to the signal being converted. The ADS805 samples the input signal on the rising edge of the CLK input. Therefore, this edge should have the lowest possible jitter. The jitter noise contribution to total SNR is given by the following equation. If this value is near your system requirements, input clock jitter must be reduced.

$$JitterSNR = 20 \log \frac{1}{2\pi f_{IN} t_A} \text{ rms signal to rms noise}$$

Where:  $f_{IN}$  is Input Signal Frequency

$t_A$  is rms Clock Jitter

Particularly in undersampling applications, special consideration should be given to clock jitter. The clock input should be treated as an analog input in order to achieve the highest level of performance. Any overshoot or undershoot of the clock signal may cause degradation of the performance. When digitizing at high sampling rates, the clock should have a 50% duty cycle ( $t_H = t_L$ ), along with fast rise and fall times of 2ns or less.

### DIGITAL OUTPUTS

The digital outputs of the ADS805 are designed to be compatible with both high speed TTL and CMOS logic families. The driver stage for the digital outputs is supplied through a separate supply pin, VDRV, which is not connected to the analog supply pins. By adjusting the voltage on VDRV, the digital output levels will vary respectively. Therefore, it is possible to operate the ADS805 on a +5V analog supply while interfacing the digital outputs to 3V-logic with the VDRV pin tied to the +3V digital supply.

It is recommended to keep the capacitive loading on the data lines as low as possible ( $\leq 15\text{pF}$ ). Larger capacitive loads demand higher charging currents as the output are changing. Those high current surges can feed back to the analog portion of the ADS805 and influence the performance. If

necessary, external buffers or latches may be used which provide the added benefit of isolating the ADS805 from any digital noise activities on the bus coupling back high frequency noise. In addition, resistors in series with each data line may help maintain the ac performance of the ADS805. Their use depends on the capacitive loading seen by the converter. Values in the range of  $100\Omega$  to  $200\Omega$  will limit the instantaneous current the output stage has to provide for recharging the parasitic capacitances, as the output levels change from L to H or H to L.

### GROUNDING AND DECOUPLING

Proper grounding and bypassing, short lead length, and the use of ground planes are particularly important for high frequency designs. Multi-layer PC boards are recommended for best performance since they offer distinct advantages like minimizing ground impedance, separation of signal layers by ground layers, etc. It is recommended that the analog and digital ground pins of the ADS805 be joined together at the IC and be connected only to the analog ground of the system.

The ADS805 has analog and digital supply pins, however the converter should be treated as an analog component and all supply pins should be powered by the analog supply. This will ensure the most consistent results, since digital supply lines often carry high levels of noise that would otherwise be coupled into the converter and degrade the achievable performance.

Because of the pipeline architecture, the converter also generates high frequency current transients and noise that are fed back into the supply and reference lines. This requires that the supply and reference pins be sufficiently bypassed. Figure 12 shows the recommended decoupling scheme for the analog supplies. In most cases,  $0.1\mu\text{F}$  ceramic chip capacitors are adequate to keep the impedance low over a wide frequency range. Their effectiveness largely depends on the proximity to the individual supply pin. Therefore, they should be located as close to the supply pins as possible. In addition, a larger size bipolar capacitor ( $1\mu\text{F}$  to  $22\mu\text{F}$ ) should be placed on the PC board in close proximity to the converter circuit.

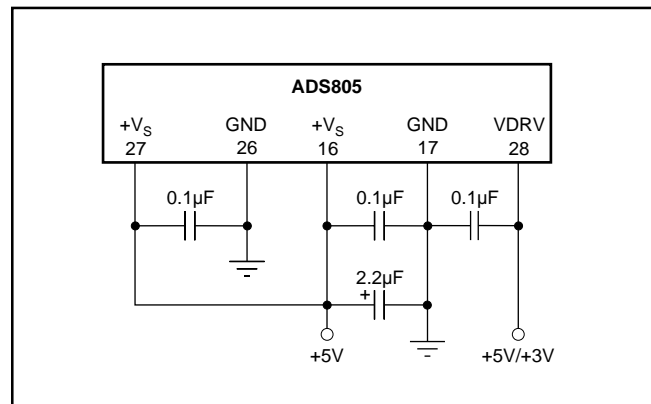

FIGURE 12. Recommended Bypassing for Analog Supply Pins.
