●Circuit operation

(1) Hall input ~ output

The 3-phase Hall signal is amplified in the hall amplifiers and sent to the matrix section, where the signal is further amplified and combined. After the signal is converted to a current in the amplitude control circuit, the current is supplied to the output driver, which then provides a motor drive current. The phases of the Hall input signal, output voltage, and output current are shown in Fig. 5.

Fig. 5

(2) Torque control pin

The  $R_{NF}$ -pin current depends on the torque control input voltage ( $E_C$ ) as shown in Fig. 6.

Fig. 6

	Reverse pin voltage	
	H	L
$E_{CR} < E_C$	Reverse	Forward
$E_{CR} > E_C$	Stop	Reverse

(3) Start / stop pin

The motor is in the run mode when the pin input voltage is 3.5V or more, and in the idle mode (all output transistors are off) when the voltage is 1.5V or less.

(4) Power ground pin ( $R_{NF}$  pin)

The  $R_{NF}$  pin is the output stage ground pin. Connect a resistor ( $0.5\Omega$  recommended) between this pin and the ground to monitor the output current.

(5) Phase compensation pin ( $C_{NF}$  pin)

Connect and adjust a capacitor between this pin and the ground if the output tends to oscillate.

## ● Operation notes

## (1) Start / stop

The I / O equivalent circuit of the start / stop pin is shown in Fig. 7. The pin has a temperature dependence of  $-7\text{mV} / ^\circ\text{C}$ , and the resistance can vary  $\pm 30\%$ . Take the temperature effect into consideration when designing your application.

## (2) Hall input

The Hall input equivalent circuit is shown in Fig. 12. The Hall devices can be connected in either series or parallel.

## (3) Thermal shutdown circuit (TSD)

The circuit puts the coil outputs ( $A_1$ ,  $A_2$ , and  $A_3$ ) to the open state at the temperature of  $175^\circ\text{C}$  (typical). There is a temperature difference of about  $15^\circ\text{C}$  between the temperatures at which the circuit is activated and deactivated.
