description

The 74AC11898 features AND-gated serial inputs and an asynchronous clear. The gated serial inputs (A and B) permit complete control over incoming data. A low at either input inhibits entry of new data and resets the first flip-flop to the low level on the rising edge of the next clock pulse. A high-level input enables the other input, which then determines the state of the first flip-flop. Data at the serial inputs may be changed while the clock is high or low provided the minimum setup and hold time requirements are met. Clocking occurs on the low-to-high transition of the clock input.

The 74AC11898 is characterized for operation from –40°C to 85°C.

FUNCTION TABLE

INPUTS				OUTPUTS			
$\overline{CLR}$	CLK	A	B	Q_A	Q_B	...	Q_J
L	X	X	X	L	L		L
H	L	X	X	Q_{A0}	Q_{B0}		Q_{JO}
H	↑	H	H	H	Q_{AN}		Q_{IN}
H	↑	L	X	L	Q_{AN}		Q_{IN}
H	↑	X	L	L	Q_{AN}		Q_{IN}

H = high level (steady state)
X = irrelevant (any input, including transitions)
↑ = transition from low to high level
Q_{A0}, Q_{B0}, Q_{J0} = the level of Q_A, Q_B, Q_J respectively, before the indicated steady-state input conditions were established.
Q_n, Q_{in} = the level or Q_A or Q_J before the most recent ↑ transition of the clock; indicates a one-bit shift.

† Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

NOTE 1: The input and output voltage ratings may be exceeded if the input and output clamp-current ratings are observed.
