

PHASE-LOCKED-LOOP WITH VCO

FEATURES

- Low power consumption
- Centre frequency of up to 17 MHz (typ.) at  $V_{CC} = 4.5\text{ V}$
- Choice of three phase comparators: EXCLUSIVE-OR; edge-triggered JK flip-flop; edge-triggered RS flip-flop
- Excellent VCO frequency linearity
- VCO-inhibit control for ON/OFF keying and for low standby power consumption
- Minimal frequency drift
- Operating power supply voltage range: VCO section 3.0 to 6.0 V digital section 2.0 to 6.0 V
- Zero voltage offset due to op-amp buffering
- Output capability: standard
- I<sub>CC</sub> category: MSI

SYMBOL	PARAMETER	CONDITIONS	TYPICAL		UNIT
			HC	HCT	
$f_o$	VCO centre frequency	$C_1 = 40\text{ pF}$ $R_1 = 3\text{ k}\Omega$ $V_{CC} = 5\text{ V}$	19	19	MHz
$C_1$	input capacitance (pin 5)		3.5	3.5	pF
$C_{PD}$	power dissipation capacitance per package	notes 1 and 2	24	24	pF

GND = 0 V;  $T_{amb} = 25\text{ }^\circ\text{C}$

Notes

1.  $C_{PD}$  is used to determine the dynamic power dissipation ( $P_D$  in  $\mu\text{W}$ ):

$$P_D = C_{PD} \times V_{CC}^2 \times f_i + \sum (C_L \times V_{CC}^2 \times f_o) \text{ where:}$$

- $f_i$  = input frequency in MHz
- $f_o$  = output frequency in MHz
- $\sum (C_L \times V_{CC}^2 \times f_o)$  = sum of outputs
- $C_L$  = output load capacitance in pF
- $V_{CC}$  = supply voltage in V

2. Applies to the phase comparator section only (VCO disabled). For power dissipation of the VCO and demodulator sections see Figs 22, 23 and 24.

PACKAGE OUTLINES

- 16-lead DIL; plastic (SOT38Z).
- 16-lead mini-pack; plastic (SO16; SOT109A).

GENERAL DESCRIPTION

The 74HC/HCT4046A are high-speed Si-gate CMOS devices and are pin compatible with the "4046" of the "4000B" series. They are specified in compliance with JEDEC standard no. 7A.

The 74HC/HCT4046A are phase-locked-loop circuits that comprise a linear voltage-controlled oscillator (VCO) and three different phase comparators (PC1, PC2 and PC3) with a common signal input amplifier and a common comparator input.

The signal input can be directly coupled to large voltage signals, or indirectly coupled (with a series capacitor) to small voltage signals. A self-bias input circuit keeps small voltage signals within the linear region of the input amplifiers. With a passive low-pass filter, the "4046A" forms a second-order loop PLL. The excellent VCO linearity is achieved by the use of linear op-amp techniques.

(continued on next page)

APPLICATIONS

- FM modulation and demodulation
- Frequency synthesis and multiplication
- Frequency discrimination
- Tone decoding
- Data synchronization and conditioning
- Voltage-to-frequency conversion
- Motor-speed control

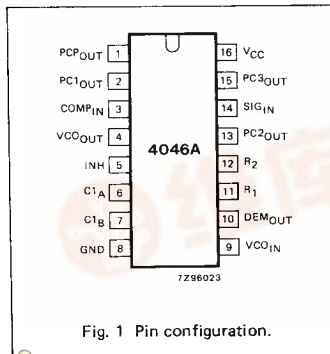

Fig. 1 Pin configuration.

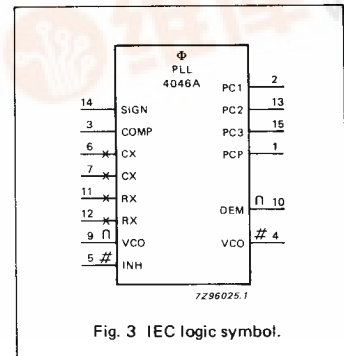

Fig. 3 IEC logic symbol.

**PIN DESCRIPTION**

PIN NO.	SYMBOL	NAME AND FUNCTION
1	PCP <sub>OUT</sub>	phase comparator pulse output
2	PC1 <sub>OUT</sub>	phase comparator 1 output
3	COMP <sub>IN</sub>	comparator input
4	VCO <sub>OUT</sub>	VCO output
5	INH	inhibit input
6	C1 <sub>A</sub>	capacitor C1 connection A
7	C1 <sub>B</sub>	capacitor C1 connection B
8	GND	ground (0 V)
9	VCO <sub>IN</sub>	VCO input
10	DEM <sub>OUT</sub>	demodulator output
11	R <sub>1</sub>	resistor R1 connection
12	R <sub>2</sub>	resistor R2 connection
13	PC2 <sub>OUT</sub>	phase comparator 2 output
14	SIG <sub>IN</sub>	signal input
15	PC3 <sub>OUT</sub>	phase comparator 3 output
16	V <sub>CC</sub>	positive supply voltage

VCO output signal has a duty factor of 50% (maximum expected deviation 1%), if the VCO input is held at a constant DC level. A LOW level at the inhibit input (INH) enables the VCO and demodulator, while a HIGH level turns both off to minimize standby power consumption.

The only difference between the HC and HCT versions is the input level specification of the INH input. This input disables the VCO section. The sections of the comparator are identical, so that there is no difference in the SIG<sub>IN</sub> (pin 14) or COMP<sub>IN</sub> (pin 3) inputs between the HC and HCT versions.

**Phase comparators**

The signal input (SIG<sub>IN</sub>) can be directly coupled to the self-biasing amplifier at pin 14, provided that the signal swing is between the standard HC family input logic levels. Capacitive coupling is required for signals with smaller swings.

**Phase comparator 1 (PC1)**

This is an EXCLUSIVE-OR network. The signal and comparator input frequencies ( $f_i$ ) must have a 50% duty factor to obtain the maximum locking range. The transfer characteristic of PC1, assuming ripple ( $f_r = 2f_i$ ) is suppressed, is:

$$V_{DEMOUT} = \frac{V_{CC}}{\pi} (\phi_{SIGIN} - \phi_{COMPIN})$$

where  $V_{DEMOUT}$  is the demodulator output at pin 10;

$V_{DEMOUT} = V_{PC1OUT}$  (via low-pass filter).

**GENERAL DESCRIPTION (Cont'd)**

**VCO**

The VCO requires one external capacitor C1 (between C1<sub>A</sub> and C1<sub>B</sub>) and one external resistor R1 (between R1 and GND) or two external resistors R1 and R2 (between R1 and GND, and R2 and GND). Resistor R1 and capacitor C1 determine the frequency range of the VCO. Resistor R2 enables the VCO to have a frequency offset if required.

The high input impedance of the VCO simplifies the design of low-pass filters by giving the designer a wide choice of

resistor/capacitor ranges. In order not to load the low-pass filter, a demodulator output of the VCO input voltage is provided at pin 10 (DEM<sub>OUT</sub>). In contrast to conventional techniques where the DEM<sub>OUT</sub> voltage is one threshold voltage lower than the VCO input voltage, here the DEM<sub>OUT</sub> voltage equals that of the VCO input. If DEM<sub>OUT</sub> is used, a load resistor (R<sub>S</sub>) should be connected from DEM<sub>OUT</sub> to GND; if unused, DEM<sub>OUT</sub> should be left open. The VCO output (VCO<sub>OUT</sub>) can be connected directly to the comparator input (COMP<sub>IN</sub>), or connected via a frequency-divider. The

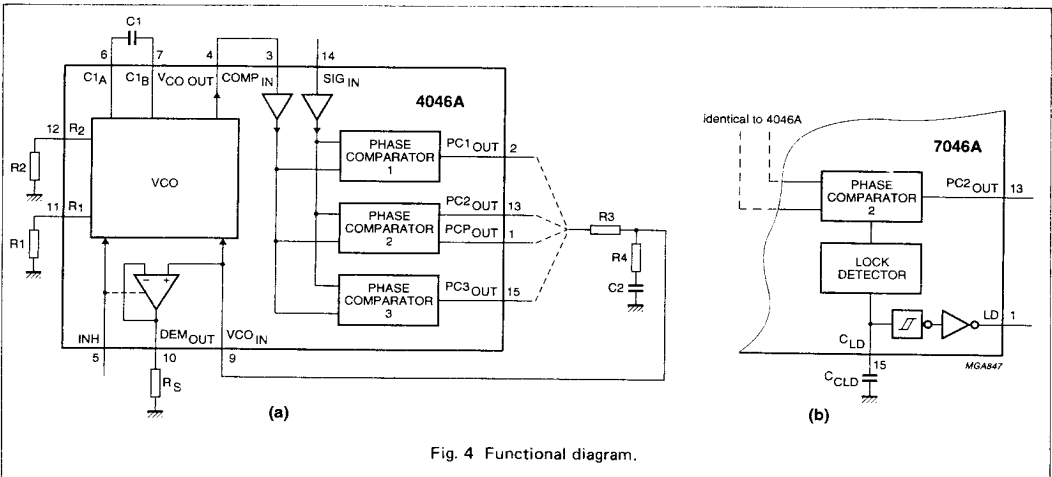

Fig. 4 Functional diagram.

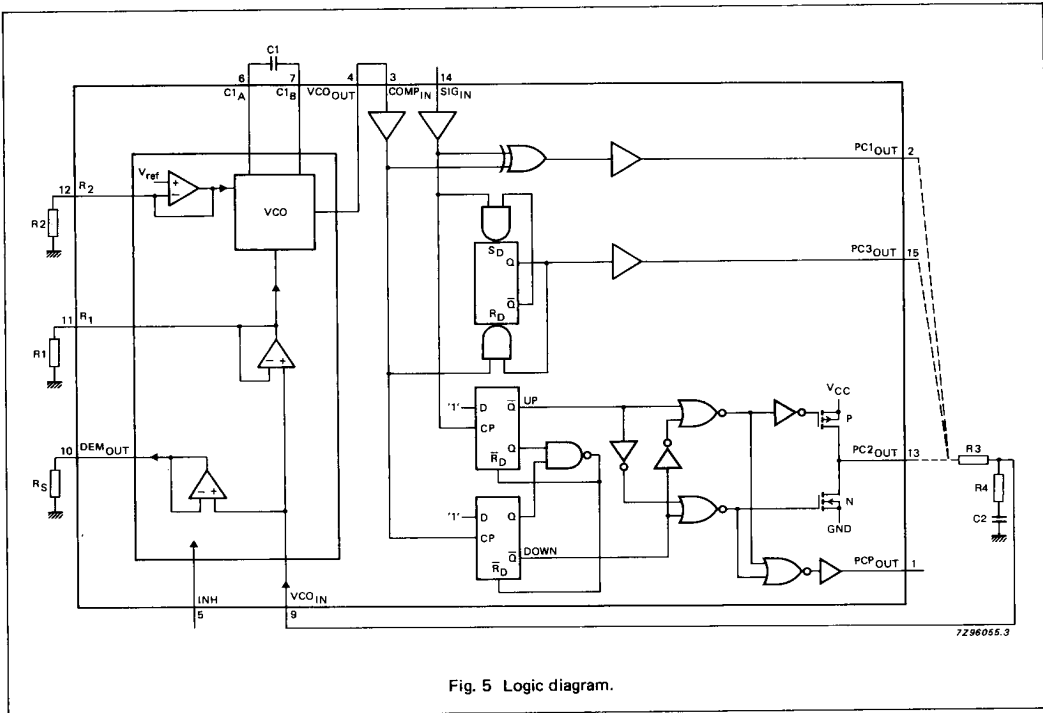

Fig. 5 Logic diagram.

The phase comparator gain is:

$$K_p = \frac{V_{CC}}{\pi} \text{ (V/r)}.$$

The average output voltage from PC1, fed to the VCO input via the low-pass filter and seen at the demodulator output at pin 10 ( $V_{DEMOUT}$ ), is the resultant of the phase differences of signals ( $SIG_{IN}$ ) and the comparator input ( $COMP_{IN}$ ) as shown in Fig. 6. The average of  $V_{DEMOUT}$  is equal to  $1/2 V_{CC}$  when there is no signal or noise at  $SIG_{IN}$  and with this input the VCO oscillates at the centre frequency ( $f_0$ ). Typical waveforms for the PC1 loop locked at  $f_0$  are shown in Fig. 7.

The frequency capture range ( $2f_c$ ) is defined as the frequency range of input signals on which the PLL will lock if it was initially out-of-lock. The frequency lock range ( $2f_l$ ) is defined as the frequency range of input signals on which the loop will stay locked if it was initially in lock. The capture range is smaller or equal to the lock range.

Fig. 6 Phase comparator 1: average output voltage versus input phase difference:

$$V_{DEMOUT} = V_{PC1OUT} =$$

$$\frac{V_{CC}}{\pi} (\phi_{SIGIN} - \phi_{COMPIN})$$

$$\phi_{DEMOUT} = (\phi_{SIGIN} - \phi_{COMPIN}).$$

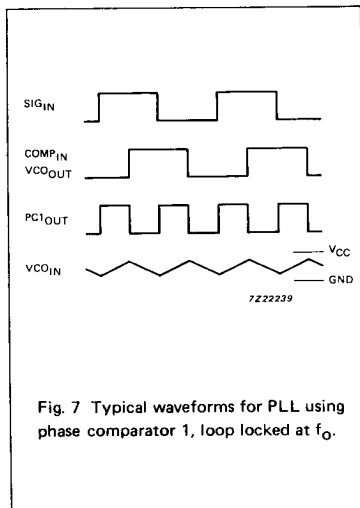

Fig. 7 Typical waveforms for PLL using phase comparator 1, loop locked at  $f_0$ .

**GENERAL DESCRIPTION (Cont'd)****Phase comparators (Cont'd)**

With PC1, the capture range depends on the low-pass filter characteristics and can be made as large as the lock range.

This configuration retains lock even with very noisy input signals. Typical behaviour of this type of phase comparator is that it can lock to input frequencies close to the harmonics of the VCO centre frequency.

**Phase comparator 2 (PC2)**

This is a positive edge-triggered phase and frequency detector. When the PLL is using this comparator, the loop is controlled by positive signal transitions and the duty factors of SIG<sub>IN</sub> and COMP<sub>IN</sub> are not important. PC2 comprises two D-type flip-flops, control-gating and a 3-state output stage. The circuit functions as an up-down counter (Fig. 5) where SIG<sub>IN</sub> causes an up-count and COMP<sub>IN</sub> a down-count. The transfer function of PC2, assuming ripple ( $f_r = f_i$ ) is suppressed, is:

$$V_{\text{DEMOUT}} = \frac{V_{\text{CC}}}{4\pi} (\phi_{\text{SIGIN}} - \phi_{\text{COMPIN}})$$

where  $V_{\text{DEMOUT}}$  is the demodulator output at pin 10;

$V_{\text{DEMOUT}} = V_{\text{PC2OUT}}$  (via low-pass filter).

The phase comparator gain is:

$$K_p = \frac{V_{\text{CC}}}{4\pi} (V/r).$$

$V_{\text{DEMOUT}}$  is the resultant of the initial phase differences of SIG<sub>IN</sub> and COMP<sub>IN</sub> as shown in Fig. 8. Typical waveforms for the PC2 loop locked at  $f_0$  are shown in Fig. 9.

When the frequencies of SIG<sub>IN</sub> and COMP<sub>IN</sub> are equal but the phase of SIG<sub>IN</sub> leads that of COMP<sub>IN</sub>, the p-type output driver at PC2OUT is held "ON" for a time corresponding to the phase difference ( $\phi_{\text{DEMOUT}}$ ). When the phase of SIG<sub>IN</sub> lags that of COMP<sub>IN</sub>, the n-type driver is held "ON".

When the frequency of SIG<sub>IN</sub> is higher than that of COMP<sub>IN</sub>, the p-type output driver is held "ON" for most of the input signal cycle time, and for the remainder of the cycle both n and p-type drivers are "OFF" (3-state). If the SIG<sub>IN</sub> frequency

is lower than the COMP<sub>IN</sub> frequency, then it is the n-type driver that is held "ON" for most of the cycle. Subsequently, the voltage at the capacitor (C2) of the low-pass filter connected to PC2OUT varies until the signal and comparator inputs are equal in both phase and frequency. At this stable point the voltage on C2 remains constant as the PC2 output is in 3-state and the VCO input at pin 9 is a high impedance. Also in this condition, the signal at the phase comparator pulse output (PCPOUT) is a HIGH level and so can be used for indicating a locked condition.

Thus, for PC2, no phase difference exists between SIG<sub>IN</sub> and COMP<sub>IN</sub> over the full frequency range of the VCO. Moreover, the power dissipation due to the low-pass filter is reduced because both p and n-type drivers are "OFF" for most of the signal input cycle. It should be noted that the PLL lock range for this type of phase comparator is equal to the capture range and is independent of the low-pass filter. With no signal present at SIG<sub>IN</sub> the VCO adjusts, via PC2, to its lowest frequency.

Fig. 8 Phase comparator 2: average output voltage versus input phase difference:

$$V_{\text{DEMOUT}} = V_{\text{PC2OUT}} =$$

$$\frac{V_{\text{CC}}}{4\pi} (\phi_{\text{SIGIN}} - \phi_{\text{COMPIN}})$$

$$\phi_{\text{DEMOUT}} = (\phi_{\text{SIGIN}} - \phi_{\text{COMPIN}}).$$

Fig. 9 Typical waveforms for PLL using phase comparator 2, loop locked at  $f_0$ .

*Phase comparator 3 (PC3)*

This is a positive edge-triggered sequential phase detector using an RS-type flip-flop. When the PLL is using this comparator, the loop is controlled by positive signal transitions and the duty factors of SIG<sub>IN</sub> and COMP<sub>IN</sub> are not important. The transfer characteristic of PC3, assuming ripple ( $f_r = f_i$ ) is suppressed, is:

$$V_{\text{DEMOUT}} = \frac{V_{\text{CC}}}{2\pi} (\phi_{\text{SIGIN}} - \phi_{\text{COMPIN}})$$

where  $V_{\text{DEMOUT}}$  is the demodulator output at pin 10;

$V_{\text{DEMOUT}} = V_{\text{PC3OUT}}$  (via low-pass filter).

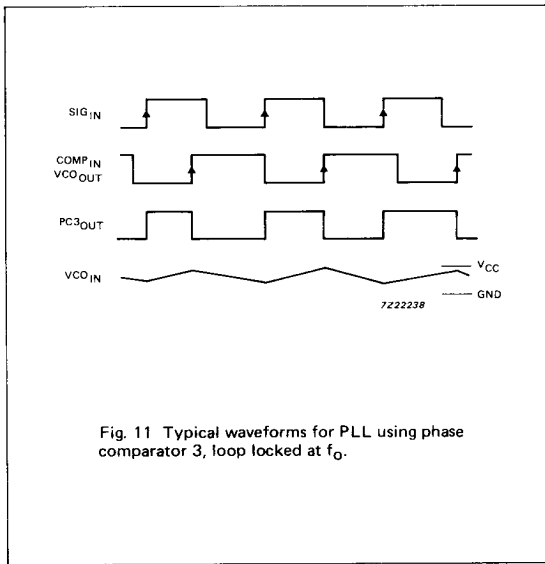

The phase comparator gain is:

$$K_p = \frac{V_{\text{CC}}}{2\pi} (V/r).$$

The average output from PC3, fed to the VCO via the low-pass filter and seen at the demodulator output at pin 10 ( $V_{\text{DEMOUT}}$ ), is the resultant of the phase differences of SIG<sub>IN</sub> and COMP<sub>IN</sub> as shown in Fig. 10. Typical waveforms for the PC3 loop locked at  $f_0$  are shown in Fig. 11.

The phase-to-output response characteristic of PC3 (Fig. 10) differs from that of PC2 in that the phase angle between SIG<sub>IN</sub> and COMP<sub>IN</sub> varies between 0° and 360° and is 180° at the

centre frequency. Also PC3 gives a greater voltage swing than PC2 for input phase differences but as a consequence the ripple content of the VCO input signal is higher. The PLL lock range for this type of phase comparator and the capture range are dependent on the low-pass filter. With no signal present at SIG<sub>IN</sub> the VCO adjusts, via PC3, to its lowest frequency.

**APPLICATION INFORMATION**

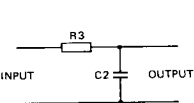

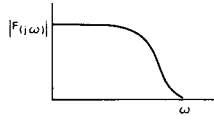

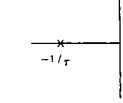

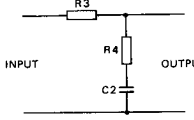

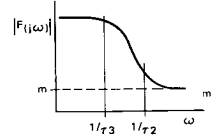

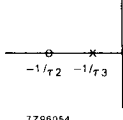

This information is a guide for the approximation of values of external components to be used with the 74HC/HCT4046A in a phase-lock-loop system.

References should be made to Figs 29, 30 and 31 as indicated in the table.

Values of the selected components should be within the following ranges:

- R1 between 3 kΩ and 300 kΩ;
- R2 between 3 kΩ and 300 kΩ;
- R1 + R2 parallel value > 2.7 kΩ;
- C1 greater than 40 pF.

APPLICATION INFORMATION (Continued)

Notes to Fig. 29

1. To obtain optimum VCO performance,  $C_1$  must be as small as possible but larger than 100 pF.
2. Interpolation for various values of  $R_1$  can be easily calculated because, a constant  $R_1 C_1$  product will produce almost the same VCO output frequency.

**Notes to Fig. 30**

1. To obtain optimum VCO performance, C1 must be as small as possible but larger than 100 pF.
2. Interpolation for various values of R2 can be easily calculated because, a constant  $R2C1$  product will produce almost the same VCO output frequency.

APPLICATION INFORMATION (Continued)

Fig. 31 Typical frequency lock range ( $2f_L$ ) versus the product  $R1C1$ :  $V_{VCOIN}$  range = 0.9 to  $(V_{CC} - 0.9)$  V;  $R2 = \infty$ ; VCO gain:

$$K_V = \frac{2f_L}{V_{VCOIN} \text{ range}} 2\pi \text{ (r/s/V)}$$

**PLL design example**

The frequency synthesizer, used in the design example shown in Fig. 32, has the following parameters:

- Output frequency: 2 MHz to 3 MHz
- frequency steps : 100 kHz
- settling time : 1 ms
- overshoot : < 20%

The open-loop gain is  $H(s) \times G(s) = K_p \times K_f \times K_o \times K_n$ .

Where:

- $K_p$  = phase comparator gain
- $K_f$  = low-pass filter transfer gain
- $K_o$  =  $K_v/s$  VCO gain
- $K_n$  =  $1/n$  divider ratio

The programmable counter ratio  $K_n$  can be found as follows:

$$N_{\min.} = \frac{f_{\text{out}}}{f_{\text{step}}} = \frac{2 \text{ MHz}}{100 \text{ kHz}} = 20$$

$$N_{\max.} = \frac{f_{\text{out}}}{f_{\text{step}}} = \frac{3 \text{ MHz}}{100 \text{ kHz}} = 30$$

The VCO is set by the values of R1, R2 and C1, R2 = 10 kΩ (adjustable).

The values can be determined using the information in the section "DESIGN CONSIDERATIONS".

With  $f_o = 2.5 \text{ MHz}$  and  $f_L = 500 \text{ kHz}$  this gives the following values ( $V_{CC} = 5.0 \text{ V}$ ):

- R1 = 10 kΩ
- R2 = 10 kΩ
- C1 = 500 pF

The VCO gain is:

$$K_v = \frac{2f_L \times 2 \times \pi}{0.9 - (V_{CC} - 0.9)} = \frac{1 \text{ MHz}}{3.2} \times 2\pi \approx 2 \times 10^6 \text{ r/s/V}$$

The gain of the phase comparator is:

$$K_p = \frac{V_{CC}}{4 \times \pi} = 0.4 \text{ V/r.}$$

The transfer gain of the filter is given by:

$$K_f = \frac{1 + \tau_2 s}{1 + (\tau_1 + \tau_2)s}$$

Where:

$$\tau_1 = R3C2 \text{ and } \tau_2 = R4C2.$$

The characteristics equation is:

$$1 + H(s) \times G(s) = 0.$$

This results in:

$$s^2 + \frac{1 + K_p \times K_v \times K_n \times \tau_2}{(\tau_1 + \tau_2)} s + \frac{K_p \times K_v \times K_n}{(\tau_1 + \tau_2)} = 0.$$

The natural frequency  $\omega_n$  is defined as follows:

$$\omega_n = \sqrt{\frac{K_p \times K_v \times K_n}{(\tau_1 + \tau_2)}}.$$

and the damping value  $\xi$  is defined as follows:

$$\xi = \frac{1}{2\omega_n} \times \frac{1 + K_p \times K_v \times K_n \times \tau_2}{(\tau_1 + \tau_2)}.$$

In Fig. 33 the output frequency response to a step of input frequency is shown.

The overshoot and settling time percentages are now used to determine  $\omega_n$ . From Fig. 33 it can be seen that the damping ratio  $\xi = 0.45$  will produce an overshoot of less than 20% and settle to within 5% at  $\omega_n t = 5$ . The required settling time is 1 ms. This results in:

$$\omega_n = \frac{5}{t} = \frac{5}{0.001} = 5 \times 10^3 \text{ r/s.}$$

Rewriting the equation for natural frequency results in:

$$(\tau_1 + \tau_2) = \frac{K_p \times K_v \times K_n}{\omega_n^2}.$$

The maximum overshoot occurs at  $N_{\max.}$ :

$$(\tau_1 + \tau_2) = \frac{0.4 \times 2 \times 10^6}{5000^2 \times 30} = 0.0011 \text{ s.}$$

When  $C2 = 470 \text{ nF}$ , then

$$R4 = \frac{(\tau_1 + \tau_2) \times 2 \times \omega_n \times \xi - 1}{K_p \times K_v \times K_n \times C2} = 315 \Omega$$

now R3 can be calculated:

$$R3 = \frac{\tau_1}{C2} - R4 = 2 \text{ k}\Omega.$$

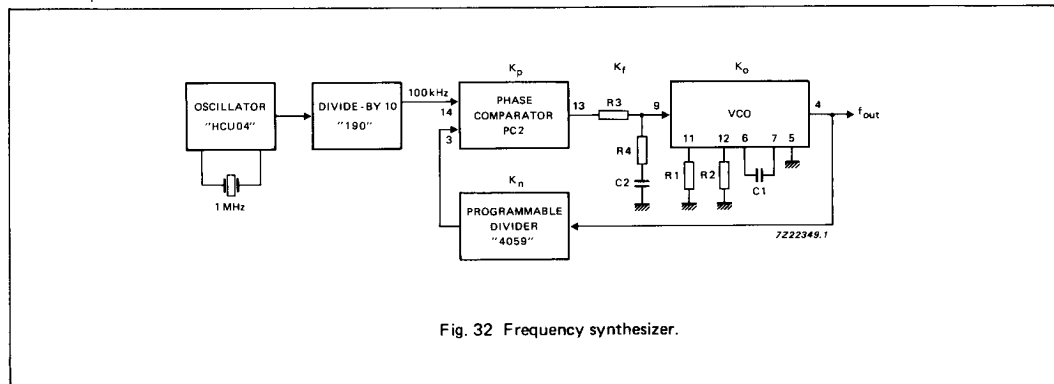

Fig. 32 Frequency synthesizer.

**Note**

For an extensive description and application example please refer to application note ordering number 9398 649 90011. Also available a computer design program for PLL's ordering number 9398 961 10061.

APPLICATION INFORMATION (Continued)

Fig. 33 Type 2, second order frequency step response.

Since the output frequency is proportional to the VCO control voltage, the PLL frequency response can be observed with an oscilloscope by monitoring pin 9 of the VCO. The average frequency response, as calculated by the Laplace method, is found experimentally by smoothing this voltage at pin 9 with a simple RC filter, whose time constant is long compared to the phase detector sampling rate but short compared to the PLL response time.

Fig. 34 Frequency compared to the time response.
