## LMV921／LMV922／LMV924

Single，Dual and Quad 1．8V，1MHz，Low Power Operational Amplifiers with Rail－To－Rail Input and Output

## General Description

The LMV921 Single／LMV922 Dual／LMV924 Quad are guar－ anteed to operate from +1.8 V to +5.0 V supply voltages and have rail－to－rail input and output．This rail－to－rail operation enables the user to make full use of the entire supply voltage range．The input common mode voltage range extends 300 mV beyond the supplies and the output can swing rail－to－rail unloaded and within 100 mV from the rail with $600 \Omega$ load at 1.8 V supply．The LMV921／LMV922／LMV924 are optimized to work at 1.8 V which make them ideal for portable two－cell battery－powered systems and single cell Li－Ion systems．
The LMV921／LMV922／LMV924 exhibit excellent speed－power ratio，achieving 1 MHz gain bandwidth product at 1.8 V supply voltage with very low supply current．The LMV921／LMV922／LMV924 are capable of driving $600 \Omega$ load and up to 1000 pF capacitive load with minimal ringing．The LMV921／LMV922／LMV924＇s high DC gain of 100dB makes them suitable for low frequency applications．
The LMV921（Single）is offered in a space saving SC70－5 and SOT23－5 packages．The SC70－5 package is only 2．0X2．1X1．0mm．These small packages are ideal solutions for area constrained PC boards and portable electronics such as cellphones and PDAs．

## Features

（Typical 1．8V Supply Values；Unless Otherwise Noted）
■ Guaranteed $1.8 \mathrm{~V}, 2.7 \mathrm{~V}$ and 5 V specifications
■ Rail－to－Rail input \＆output swing
－w／600 load
— w／2k $\Omega$ load
－ $\mathrm{V}_{\mathrm{CM}}$
－Supply current
－Gain bandwidth product
－LMV921 Maximum $\mathrm{V}_{\text {Os }}$
100 mV from rail
30 mV from rail
300 mV beyond rails
$145 \mu \mathrm{~A} /$ amplifier
1 MHz
－90dB gain w／600 load
－LMV921 available in Ultra Tiny，SC70－5 package
－LMV922 available in MSOP－8 package
－LMV924 available in TSSOP－14 package

## Applications

－Cordless／cellular phones
－Laptops
－PDAs
－PCMCIA
－Portable／battery－powered electronic Equipment
－Supply current Monitoring
－Battery monitoring

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but specific performance is not guaranteed. For guaranteed specifications and the test conditions, see the Electrical Characteristics.
Note 2: Human body model, $1.5 \mathrm{k} \Omega$ in series with 100 pF . Machine model, $200 \Omega$ in series with 100 pF .
Note 3: Applies to both single-supply and split-supply operation. Continuous short circuit operation at elevated ambient temperature can result in exceeding the maximum allowed junction temperature of $150^{\circ} \mathrm{C}$. Output currents in excess of 45 mA over long term may adversely affect reliability.

Note 4: The maximum power dissipation is a function of $T_{J(\max )}, \theta_{J A}$, and $T_{A}$. The maximum allowable power dissipation at any ambient temperature is $P_{D}=\left(T_{J(\max )}{ }^{-T} A\right) / \theta_{J A}$. All numbers apply for packages soldered directly into a PC board.
Note 5: Typical Values represent the most likely parametric norm.
Note 6: All limits are guaranteed by testing or statistical analysis.
Note 7: $\mathrm{V}^{+}=5 \mathrm{~V}$. Connected as voltage follower with 5 V step input. Number specified is the slower of the positive and negative slew rates.
Note 8: Input referred, $\mathrm{V}^{+}=5 \mathrm{~V}$ and $\mathrm{R}_{\mathrm{L}}=100 \mathrm{k} \Omega$ connected to 2.5 V . Each amp excited in turn with 1 kHz to produce $\mathrm{V}_{\mathrm{O}}=3 \mathrm{~V}_{\mathrm{Pp}}$.

Typical Performance Characteristics Unless otherwise specified, $\mathrm{v}_{\mathrm{s}}=+5 \mathrm{~V}$, single supply, $\mathrm{T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$.

*For large signal pulse response in the unity gain follower configuration, the input is 5 mV below the positive rail and 5 mV above the negative rail at $25^{\circ} \mathrm{C}$ and $85^{\circ} \mathrm{C}$. At $-40^{\circ} \mathrm{C}$, input is 10 mV below the positive rail and 10 mV above the negative rail.

## Application Note

### 1.0 Unity Gain Pulse Response Considerations

The unity-gain follower is the most sensitive configuration to capacitive loading. The LMV921/LMV922/LMV924 family can directly drive 1 nF in a unity-gain with minimal ringing. Direct capacitive loading reduces the phase margin of the amplifier. The combination of the amplifier's output impedance and the capacitive load induces phase lag. This results in either an underdamped pulse response or oscillation. The pulse response can be improved by adding a pull up resistor as shown in Figure 1

FIGURE 1. Using a Pull-Up Resistor at the Output for Stabilizing Capacitive Loads

Higher capacitances can be driven by decreasing the value of the pull-up resistor, but its value shouldn't be reduced beyond the sinking capability of the part. An alternate approach is to use an isolation resistor as illustrated in Figure 2.

10097943
FIGURE 2. Using an Isolation Resistor to Drive Heavy Capacitive Loads

### 2.0 Input Bias Current Consideration

The LMV921/LMV922/LMV924 family has a bipolar input stage. The typical input bias current $\left(I_{\mathrm{B}}\right)$ is 12 nA . The input bias current can develop a significant offset voltage. This offset is primarily due to $I_{B}$ flowing through the negative feedback resistor, $\mathrm{R}_{\mathrm{F}}$. For example, if $\mathrm{I}_{\mathrm{B}}$ is 50 nA (max room) and $R_{F}$ is $100 \mathrm{k} \Omega$, then an offset voltage of 5 mV will develop $\left(V_{O S}=I_{B} X R_{F}\right)$. Using a compensation resistor ( $R_{C}$ ), as shown in Figure 3, cancels this affect. But the input offset current (los) will still contribute to an offset voltage in the same manner.

10097959

FIGURE 3. Canceling the Voltage Offset Effect of Input Bias Current

### 3.0 Operating Supply Voltage

The LMV921/LMV922/LMV924 family is guaranteed to operate from 1.8 V to 5.0 V . They will begin to function at power voltages as low as 1.2 V at room temperature when unloaded. Start up voltage increases to 1.5 V when the amplifier is fully loaded ( $600 \Omega$ to mid-supply). Below 1.2 V the output voltage is not guaranteed to follow the input. Figure 4 below shows the output voltage vs. supply voltage with the LMV921/LMV922/LMV924 configured as a voltage follower at room temperature.

FIGURE 4.

### 4.0 Input and Output Stage

The rail-to-rail input stage of this family provides more flexibility for the designer. The LMV921/LMV922/LMV924 use a complimentary PNP and NPN input stage in which the PNP stage senses common mode voltage near $\mathrm{V}^{-}$and the NPN stage senses common mode voltage near $\mathrm{V}^{+}$. The transition from the PNP stage to NPN stage occurs 1 V below $\mathrm{V}^{+}$. Since both input stages have their own offset voltage, the offset of

## Application Note (Continued)

the amplifier becomes a function of the input common mode voltage and has a crossover point at 1 V below $\mathrm{V}^{+}$as shown in the $\mathrm{V}_{\mathrm{OS}} \mathrm{vs}$. $\mathrm{V}_{\mathrm{CM}}$ curves.
This $\mathrm{V}_{\mathrm{OS}}$ crossover point can create problems for both DC and $A C$ coupled signals if proper care is not taken. For large input signals that include the $\mathrm{V}_{\mathrm{OS}}$ crossover point in their dynamic range, this will cause distortion in the output signal. One way to avoid such distortion is to keep the signal away from the crossover. For example, in a unity gain buffer configuration and with $\mathrm{V}_{\mathrm{S}}=5 \mathrm{~V}$, a 5 V peak-to-peak signal will contain input-crossover distortion while a 3 V peak-to-peak signal centered at 1.5 V will not contain input-crossover distortion as it avoids the crossover point. Another way to avoid large signal distortion is to use a gain of -1 circuit which avoids any voltage excursions at the input terminals of the amplifier. In that circuit, the common mode DC voltage can be set at a level away from the $\mathrm{V}_{\mathrm{OS}}$ cross-over point.
For small signals, this transition in $\mathrm{V}_{\mathrm{Os}}$ shows up as a $\mathrm{V}_{\mathrm{CM}}$ dependent spurious signal in series with the input signal and can effectively degrade small signal parameters such as gain and common mode rejection ratio. To resolve this problem, the small signal should be placed such that it avoids the $\mathrm{V}_{\mathrm{Os}}$ crossover point.
In addition to the rail-to-rail performance, the output stage can provide enough output current to drive $600 \Omega$ loads. Because of the high current capability, care should be taken not to exceed the $150^{\circ} \mathrm{C}$ maximum junction temperature specification.

### 5.0 Power-Supply Considerations

The LMV921/LMV922/LMV924 are ideally suited for use with most battery-powered systems. The LMV921/LMV922/

LMV924 operate from a single +1.8 V to +5.0 V supply and consumes about $145 \mu \mathrm{~A}$ of supply current per Amplifier. A high power supply rejection ratio of 78 dB allows the amplifier to be powered directly off a decaying battery voltage extending battery life.
Table 1 lists a variety of typical battery types. Batteries have different voltage ratings; operating voltage is the battery voltage under nominal load. End-of-Life voltage is defined as the voltage at which $100 \%$ of the usable power of the battery is consumed. Table 1 also shows the typical operating time of the LMV921.

### 6.0 Distortion

The two main contributors of distortion in LMV921/LMV922/ LMV924 family is:

1. Output crossover distortion occurs as the output transitions from sourcing current to sinking current.
2. Input crossover distortion occurs as the input switches from NPN to PNP transistor at the input stage.
To decrease crossover distortion:
3. Increase the load resistance. This lowers the output crossover distortion but has no effect on the input crossover distortion.
4. Operate from a single supply with the output always sourcing current.
5. Limit the input voltage swing for large signals between ground and one volt below the positive supply.
6. Operate in inverting configuration to eliminate common mode induced distortion.
7. Avoid small input signal around the input crossover region. The discontinuity in the offset voltage will effect the gain, CMRR and PSRR.

TABLE 1. LMV921 Characteristics with Typical Battery Systems.

| Battery Type | Operating <br> Voltage (V) | End-of-Life <br> Voltage (V) | Capacity AA <br> Size (mA - h) | LMV921 <br> Operating <br> time (Hours) |

## Typical Applications

1.0 Half-wave Rectifier with Rail-To-Ground Output Swing
Since the LMV921 input common mode range includes both positive and negative supply rails and the output can also swing to either supply, achieving half-wave rectifier functions in either direction is an easy task. All that is needed are two external resistors; there is no need for diodes or matched resistors. The half wave rectifier can have either positive or negative going outputs, depending on the way the circuit is arranged.

In Figure 5 the circuit is referenced to ground, while in Figure 6 the circuit is biased to the positive supply. These configurations implement the half wave rectifier since the LMV921 can not respond to one-half of the incoming waveform. It can not respond to one-half of the incoming because the amplifier can not swing the output beyond either rail therefore the output disengages during this half cycle. During the other half cycle, however, the amplifier achieves a half wave that can have a peak equal to the total supply voltage. $R_{1}$ should be large enough not to load the LMV921.

## Typical Applications (Continued)

### 2.0 Instrumentation Amplifier with Rail-To-Rail Input and Output

Using three of the LMV924 Amplifiers, an instrumentation amplifier with rail-to-rail inputs and outputs can be made.
Some manufacturers use a precision voltage divider array of 5 resistors to divide the common mode voltage to get a rail-to-rail input range. The problem with this method is that it also divides the signal, so in order to get unity gain, the amplifier must be run at high loop gains. This raises the noise and drift by the internal gain factor and lowers the input impedance. Any mismatch in these precision resistors reduces the CMRR as well. Using the LMV924 eliminates all of these problems.
In this example, amplifiers A and B act as buffers to the differential stage. These buffers assure that the input imped-
ance is very high and require no precision matched resistors in the input stage. They also assure that the difference amp is driven from a voltage source. This is necessary to maintain the CMRR set by the matching $R_{1}-R_{2}$ with $R_{3}-R_{4}$.
The gain is set by the ratio of $R_{2} / R_{1}$ and $R_{3}$ should equal $R_{1}$ and $\mathrm{R}_{4}$ equal $\mathrm{R}_{2}$.
With both rail-to-rail input and output ranges, the input and output are only limited by the supply voltages. Remember that even with rail-to-rail outputs, the output can not swing past the supplies so the combined common mode voltages plus the signal should not be greater that the supplies or limiting will occur. For additional applications, see National Semiconductor application notes AN-29, AN-31, AN-71, and AN-127.
