TMS320VC5416
FIXED-POINT DIGITAL SIGNAL PROCESSOR

SPRS095E – MARCH 1999 – REVISED MAY 2000

PRODUCT PREVIEW

- Advanced Multibus Architecture With Three Separate 16-Bit Data Memory Buses and One Program Memory Bus
- 40-Bit Arithmetic Logic Unit (ALU) Including a 40-Bit Barrel Shifter and Two Independent 40-Bit Accumulators
- 17- × 17-Bit Parallel Multiplier Coupled to a 40-Bit Dedicated Adder for Non-Pipelined Single-Cycle Multiply/Accumulate (MAC) Operation
- Compare, Select, and Store Unit (CSSU) for the Add/Compare Selection of the Viterbi Operator
- Exponent Encoder to Compute an Exponent Value of a 40-Bit Accumulator Value in a Single Cycle
- Two Address Generators With Eight Auxiliary Registers and Two Auxiliary Register Arithmetic Units (ARAUs)
- Data Bus With a Bus Holder Feature
- Extended Addressing Mode for 8M × 16-Bit Maximum Addressable External Program Space
- 128K x 16-Bit On-Chip RAM Composed of:
  - Eight Blocks of 8K × 16-Bit On-Chip Dual-Access Program/Data RAM
  - Eight Blocks of 8K × 16-Bit On-Chip Single-Access Program RAM
- 16K × 16-Bit On-Chip ROM Configured for Program Memory
- Enhanced External Parallel Interface (XIO2)
- Single-Instruction-Repeat and Block-Repeat Operations for Program Code
- Block-Memory-Move Instructions for Better Program and Data Management
- Instructions With a 32-Bit Long Word Operand
- Instructions With Two- or Three-Operand Reads
- Arithmetic Instructions With Parallel Store and Parallel Load
- Conditional Store Instructions
- Fast Return From Interrupt
- On-Chip Peripherals
  - Software-Programmable Wait-State Generator and Programmable Bank-Switching
  - On-Chip Programmable Phase-Locked Loop (PLL) Clock Generator With Internal Oscillator or External Clock Source
  - One 16-Bit Timer
  - Six-Channel Direct Memory Access (DMA) Controller
  - Three Multichannel Buffered Serial Ports (McBSPs)
  - 8/16-Bit Enhanced Parallel Host-Port Interface (HPI8/16)
- Power Consumption Control With IDLE1, IDLE2, and IDLE3 Instructions With Power-Down Modes
- CLKOUT Off Control to Disable CLKOUT
- On-Chip Scan-Based Emulation Logic, IEEE Std 1149.1† (JTAG) Boundary Scan Logic
- 144-Pin Thin Quad Flatpack (TQFP) (PGE Suffix)
- 144-Pin Ball Grid Array (BGA) (GGU Suffix)
- 6.25-ns Single-Cycle Fixed-Point Instruction Execution Time (160 MIPS)
- 3.3-V I/O Supply Voltage
- 1.5-V Core Supply Voltage

description

The TMS320VC5416 fixed-point, digital signal processor (DSP) (hereafter referred to as the ’5416 unless otherwise specified) is based on an advanced modified Harvard architecture that has one program memory bus and three data memory buses. This processor provides an arithmetic logic unit (ALU) with a high degree of parallelism, application-specific hardware logic, on-chip memory, and additional on-chip peripherals. The basis of the operational flexibility and speed of this DSP is a highly specialized instruction set.

† IEEE Standard 1149.1-1990 Standard-Test-Access Port and Boundary Scan Architecture.

description (continued)

Separate program and data spaces allow simultaneous access to program instructions and data, providing a high degree of parallelism. Two read operations and one write operation can be performed in a single cycle. Instructions with parallel store and application-specific instructions can fully utilize this architecture. In addition, data can be transferred between data and program spaces. Such parallelism supports a powerful set of arithmetic, logic, and bit-manipulation operations that can all be performed in a single machine cycle. The ’5416 also includes the control mechanisms to manage interrupts, repeated operations, and function calls.

NOTE: This data sheet is designed to be used in conjunction with the *TMS320C5000 DSP Family Functional Overview* (literature number SPRU307).

PRODUCT PREVIEW

terminal functions

The terminal functions table lists each signal, function, and operating mode(s) grouped by function.

Terminal Functions

TERMINAL NAME		I/O†	DESCRIPTION
DATA SIGNALS			
A22 A21 A20 A19 A18 A17 A16 A15 A14 A13 A12 A11 A10 A9 A8 A7 A6 A5 A4 A3 A2 A1 A0	(MSB) (LSB)	I/O/Z‡§	Parallel address bus A22 [most significant bit (MSB)] through A0 [least significant bit (LSB)]. The sixteen LSB lines, A0 to A15, are multiplexed to address external memory (program, data) or I/O. The seven MSB lines, A16 to A22, address external program space memory. A22–A0 is placed in the high-impedance state in the hold mode. A22–A0 also goes into the high-impedance state when $\overline{OFF}$ is low. The address bus has a bus holder feature that eliminates passive components and the power dissipation associated with them. The bus holder keeps the address bus at the previous logic level when the bus goes into a high-impedance state. A17–A0 are inputs in HPI16 mode. These pins can be used to address internal memory via the host-port interface (HPI) when the HPI16 pin is high. These pins also have Schmitt trigger inputs.
D15 D14 D13 D12 D11 D10 D9 D8 D7 D6 D5 D4 D3 D2 D1 D0	(MSB) (LSB)	I/O/Z§	Parallel data bus D15 (MSB) through D0 (LSB). D15–D0 is multiplexed to transfer data between the core CPU and external data/program memory or I/O devices or HPI in HPI16 mode (when HPI16 pin is high). D15–D0 is placed in the high-impedance state when not outputting data or when $\overline{RS}$ or $\overline{HOLD}$ is asserted. D15–D0 also goes into the high-impedance state when $\overline{OFF}$ is low. The data bus has a bus holder feature that eliminates passive components and the power dissipation associated with them. The bus holder keeps the data bus at the previous logic level when the bus goes into the high-impedance state. The bus holders on the data bus can be enabled/disabled under software control.

† I = Input, O = Output, Z = High-impedance, S = Supply

Terminal Functions (Continued)

TERMINAL NAME	I/O†	DESCRIPTION
INITIALIZATION, INTERRUPT AND RESET OPERATIONS		
$\overline{IACK}$	O/Z	Interrupt acknowledge signal. $\overline{IACK}$ indicates receipt of an interrupt and that the program counter is fetching the interrupt vector location designated by A15–A0. $\overline{IACK}$ also goes into the high-impedance state when $\overline{OFF}$ is low.
$\overline{INT0}$‡ $\overline{INT1}$‡ $\overline{INT2}$‡ $\overline{INT3}$‡	I	External user interrupt inputs. $\overline{INT0}$–$\overline{INT3}$ are maskable and are prioritized by the interrupt mask register (IMR) and the interrupt mode bit. INT0 –INT3 can be polled and reset by way of the interrupt flag register (IFR).
$\overline{NMI}$‡	I	Nonmaskable interrupt. $\overline{NMI}$ is an external interrupt that cannot be masked by way of the INTM or the IMR. When $\overline{NMI}$ is activated, the processor traps to the appropriate vector location.
$\overline{RS}$‡	I	Reset. $\overline{RS}$ causes the digitial signal processor (DSP) to terminate execution and forces the program counter to 0FF80h. When $\overline{RS}$ is brought to a high level, execution begins at location 0FF80h of program memory. $\overline{RS}$ affects various registers and status bits.
MP/$\overline{MC}$	I	Microprocessor/microcomputer mode select. If active low at reset, microcomputer mode is selected, and the internal program ROM is mapped into the upper 16K words of program memory space. If the pin is driven high during reset, microprocessor mode is selected, and the on-chip ROM is removed from program space. This pin is only sampled at reset, and the MP/$\overline{MC}$ bit of the processor mode status (PMST) register can override the mode that is selected at reset.
MULTIPROCESSING SIGNALS		
$\overline{BIO}$‡	I	Branch control. A branch can be conditionally executed when $\overline{BIO}$ is active. If low, the processor executes the conditional instruction. The $\overline{BIO}$ condition is sampled during the decode phase of the pipeline for the XC instruction, and all other instructions sample $\overline{BIO}$ during the read phase of the pipeline.
XF	O/Z	External flag output (latched software-programmable signal). XF is set high by the SSBX XF instruction, set low by RSBX XF instruction or by loading ST1. XF is used for signaling other processors in multiprocessor configurations or used as a general-purpose output pin. XF goes into the high-impedance state when $\overline{OFF}$ is low, and is set high at reset.
MEMORY CONTROL SIGNALS		
$\overline{DS}$ $\overline{PS}$ $\overline{IS}$	O/Z	Data, program, and I/O space select signals. $\overline{DS}$, $\overline{PS}$, and $\overline{IS}$ are always high unless driven low for communicating to a particular external space. Active period corresponds to valid address information. $\overline{DS}$, $\overline{PS}$, and $\overline{IS}$ are placed into the high-impedance state in the hold mode; these signals also go into the high-impedance state when $\overline{OFF}$ is low.
$\overline{MSTRB}$	O/Z	Memory strobe signal. $\overline{MSTRB}$ is always high unless low-level asserted to indicate an external bus access to data or program memory. $\overline{MSTRB}$ is placed in the high-impedance state in the hold mode; it also goes into the high-impedance state when $\overline{OFF}$ is low.
READY	I	Data ready. READY indicates that an external device is prepared for a bus transaction to be completed. If the device is not ready (READY is low), the processor waits one cycle and checks READY again. Note that the processor performs ready detection if at least two software wait states are programmed. The READY signal is not sampled until the completion of the software wait states.
R/$\overline{W}$	O/Z	Read/write signal. R/$\overline{W}$ indicates transfer direction during communication to an external device. R/$\overline{W}$ is normally in the read mode (high), unless it is asserted low when the DSP performs a write operation. R/$\overline{W}$ is placed in the high-impedance state in the hold mode; and it also goes into the high-impedance state when $\overline{OFF}$ is low.
$\overline{IOSTRB}$	O/Z	I/O strobe signal. $\overline{IOSTRB}$ is always high unless low-level asserted to indicate an external bus access to an I/O device. $\overline{IOSTRB}$ is placed in the high-impedance state in the hold mode; it also goes into the high-impedance state when $\overline{OFF}$ is low.
$\overline{HOLD}$	I	Hold input. $\overline{HOLD}$ is asserted to request control of the address, data, and control lines. When acknowledged by the 'VC5416, these lines go into the high-impedance state.

† I = Input, O = Output, Z = High-impedance, S = Supply
‡ These pins have Schmitt trigger inputs.
§ This pin has an internal bus holder controlled by way of the BSCR register.
¶ This pin has an internal pullup resistor.
# This pin has an internal pulldown resistor.

Terminal Functions (Continued)

TERMINAL NAME	I/O†	DESCRIPTION
MEMORY CONTROL SIGNALS (CONTINUED)		
$\overline{\text{HOLDA}}$	O/Z	Hold acknowledge. $\overline{\text{HOLDA}}$ indicates to the external circuitry that the processor is in a hold state and that the address, data, and control lines are in the high-impedance state, allowing them to be available to the external circuitry. $\overline{\text{HOLDA}}$ also goes into the high-impedance state when $\overline{\text{OFF}}$ is low.
$\overline{\text{MSC}}$	O/Z	Microstate complete. $\overline{\text{MSC}}$ indicates completion of all software wait states. When two or more software wait states are enabled, the $\overline{\text{MSC}}$ pin goes active at the beginning of the first software wait state and goes inactive high at the beginning of the last software wait state. If connected to the READY input, $\overline{\text{MSC}}$ forces one external wait state after the last internal wait state is completed. $\overline{\text{MSC}}$ also goes into the high-impedance state when $\overline{\text{OFF}}$ is low.
$\overline{\text{IAQ}}$	O/Z	Instruction acquisition signal. $\overline{\text{IAQ}}$ is asserted (active low) when there is an instruction address on the address bus and goes into the high-impedance state when $\overline{\text{OFF}}$ is low.
OSCILLATOR/TIMER SIGNALS		
CLKOUT	O/Z	Clock output signal. CLKOUT can represent the machine-cycle rate of the CPU divided by 1, 2, 3, or 4 as configured in the bank-switching control register (BSCR). Following reset, CLKOUT represents the machine-cycle rate divided by 4.
CLKMD1‡ CLKMD2‡ CLKMD3‡	I	Clock mode select signals. CLKMD1–CLKMD3 allows the selection and configuration of different clock modes such as crystal, external clock, and PLL mode. The external CLKMD1–CLKMD3 pins are sampled to determine the desired clock generation mode while $\overline{\text{RS}}$ is low. Following reset, the clock generation mode can be reconfigured by writing to the internal clock mode register in software. However, the oscillator enable/disable selection is performed independently of the state of $\overline{\text{RS}}$; therefore, if CLKMD1–CLKMD3 are changed following reset, the oscillator enable/disable selection may change, but other aspects of the clock generation mode will not.
X2/CLKIN	I	Clock/oscillator input. If the internal oscillator is not being used, X2/CLKIN functions as the clock input.
X1	O	Output pin from the internal oscillator for the crystal. If the internal oscillator is not used, X1 should be left unconnected. X1 does not go into the high-impedance state when $\overline{\text{OFF}}$ is low.
TOUT	O	Timer output. TOUT signals a pulse when the on-chip timer counts down past zero. The pulse is one CLKOUT cycle wide. TOUT also goes into the high-impedance state when $\overline{\text{OFF}}$ is low.
MULTICHANNEL BUFFERED SERIAL PORT 0 (McBSP #0), MULTICHANNEL BUFFERED SERIAL PORT 1 (McBSP #1), AND MULTICHANNEL BUFFERED SERIAL PORT 2 (McBSP #2) SIGNALS		
BCLKR0‡ BCLKR1‡ BCLKR2‡	I/O/Z	Receive clock input. BCLKR can be configured as an input or an output; it is configured as an input following reset. BCLKR serves as the serial shift clock for the buffered serial port receiver.
BDR0 BDR1 BDR2	I	Serial data receive input
BFSR0 BFSR1 BFSR2	I/O/Z	Frame synchronization pulse for receive input. BFSR can be configured as an input or an output; it is configured as an input following reset. The BFSR pulse initiates the receive data process over BDR.
BCLKX0‡ BCLKX1‡ BCLKX2‡	I/O/Z	Transmit clock. BCLKX serves as the serial shift clock for the McBSP transmitter. BCLKX can be configured as an input or an output, and is configured as an input following reset. BCLKX enters the high-impedance state when $\overline{\text{OFF}}$ goes low.
BDX0 BDX1 BDX2	O/Z	Serial data transmit output. BDX is placed in the high-impedance state when not transmitting, when $\overline{\text{RS}}$ is asserted, or when $\overline{\text{OFF}}$ is low.
BFSX0 BFSX1 BFSX2	I/O/Z	Frame synchronization pulse for transmit input/output. The BFSX pulse initiates the data transmit process over BDX. BFSX can be configured as an input or an output, and is configured as an input following reset. BFSX goes into the high-impedance state when $\overline{\text{OFF}}$ is low.

† I = Input, O = Output, Z = High-impedance, S = Supply
‡ These pins have Schmitt trigger inputs.
§ This pin has an internal bus holder controlled by way of the BSCR register.
¶ This pin has an internal pullup resistor.
# This pin has an internal pulldown resistor.

Terminal Functions (Continued)

TERMINAL NAME	I/O†	DESCRIPTION
HOST-PORT INTERFACE SIGNALS		
HD0–HD7‡§	I/O/Z	Parallel bidirectional data bus. The HPI data bus is used by a host device bus to exchange information with the HPI registers. These pins can also be used as general-purpose I/O pins. HD0–HD7 is placed in the high-impedance state when not outputting data or when $\overline{OFF}$ is low. The HPI data bus includes bus holders to reduce the static power dissipation caused by floating, unused pins. When the HPI data bus is not being driven by the '5416, the bus holders keep the pins at the previous logic level. The HPI data bus holders are disabled at reset and can be enabled/disabled via the HBH bit of the BSCR.
HCNTL0¶ HCNTL1¶	I	Control inputs. HCNTL0 and HCNTL1 select a host access to one of the three HPI registers. The control inputs have internal pull-ups that are only enabled when HPIENA = 0. These pins are not used when HPI16 = 1.
HBIL¶	I	Byte identification. HBIL identifies the first or second byte of transfer. The HPIL input has an internal pullup resistor that is only enabled when HPIENA = 0. This pin is not used when HPI16 = 1.
$\overline{HCS}$‡¶	I	Chip select. $\overline{HCS}$ is the select input for the HPI and must be driven low during accesses. The chip select input has an internal pullup resistor that is only enabled when HPIENA = 0.
$\overline{HDS1}$‡¶ $\overline{HDS2}$‡¶	I	Data strobe. $\overline{HDS1}$ and $\overline{HDS2}$ are driven by the host read and write strobes to control the transfer. The strobe inputs have internal pullup resistors that are only enabled when HPIENA = 0.
$\overline{HAS}$‡¶	I	Address strobe. Host with multiplexed address and data pins requires $\overline{HAS}$ to latch the address in the HPIA register. $\overline{HAS}$ input has an internal pullup resistor that is only enabled when HPIENA = 0.
HR/$\overline{W}$¶	I	Read/write. HR/$\overline{W}$ controls the direction of the HPI transfer. HR/$\overline{W}$ has an internal pullup resistor that is only enabled when HPIENA = 0.
HRDY	O/Z	Ready output. HRDY goes into the high-impedance state when $\overline{OFF}$ is low. The ready output informs the host when the HPI is ready for the next transfer.
$\overline{HINT}$	O/Z	Interrupt output. This output is used to interrupt the host. When the DSP is in reset, $\overline{HINT}$ is driven high. HINT goes into the high-impedance state when $\overline{OFF}$ is low. This pin is not used when HPI16 = 1.
HPIENA#	I	HPI module select. HPIENA must be tied to DV_{DD} to have HPI selected. If HPIENA is left open or connected to ground, the HPI module is not selected, internal pullup for the HPI input pins are enabled, and the HPI data bus has holders set. HPIENA is provided with an internal pulldown resistor that is active only when $\overline{RS}$ is low. HPIENA is sampled when $\overline{RS}$ goes high and is ignored until $\overline{RS}$ goes low again.
HPI16#	I	HPI16 mode selection.
SUPPLY PNS		
CV_{SS}	S	Ground. Dedicated ground for the core CPU.
CV_{DD}	S	$+V_{DD}$. Dedicated power supply for the core CPU.
DV_{SS}	S	Ground. Dedicated ground for I/O pins.
DV_{DD}	S	$+V_{DD}$. Dedicated power supply for I/O pins.

PRODUCT PREVIEW

Terminal Functions (Continued)

TERMINAL NAME	I/O†	DESCRIPTION
TEST PINS		
TCK‡¶	I	IEEE standard 1149.1 test clock. TCK is normally a free-running clock signal with a 50% duty cycle. The changes on test access port (TAP) of input signals TMS and TDI are clocked into the TAP controller, instruction register, or selected test data register on the rising edge of TCK. Changes at the TAP output signal (TDO) occur on the falling edge of TCK.
TDI¶	I	IEEE standard 1149.1 test data input. Pin with internal pullup device. TDI is clocked into the selected register (instruction or data) on a rising edge of TCK.
TDO	O/Z	IEEE standard 1149.1 test data output. The contents of the selected register (instruction or data) are shifted out of TDO on the falling edge of TCK. TDO is in the high-impedance state except when the scanning of data is in progress. TDO also goes into the high-impedance state when $\overline{\text{OFF}}$ is low.
TMS¶	I	IEEE standard 1149.1 test mode select. Pin with internal pullup device. This serial control input is clocked into the TAP controller on the rising edge of TCK.
$\overline{\text{TRST}}$#	I	IEEE standard 1149.1 test reset. $\overline{\text{TRST}}$, when high, gives the IEEE standard 1149.1 scan system control of the operations of the device. If $\overline{\text{TRST}}$ is not connected or driven low, the device operates in its functional mode, and the IEEE standard 1149.1 signals are ignored. Pin with internal pulldown device.
EMU0	I/O/Z	Emulator 0 pin. When $\overline{\text{TRST}}$ is driven low, EMU0 must be high for activation of the $\overline{\text{OFF}}$ condition. When $\overline{\text{TRST}}$ is driven high, EMU0 is used as an interrupt to or from the emulator system and is defined as input/output by way of the IEEE standard 1149.1 scan system.
EMU1/$\overline{\text{OFF}}$	I/O/Z	Emulator 1 pin/disable all outputs. When $\overline{\text{TRST}}$ is driven high, EMU1/$\overline{\text{OFF}}$ is used as an interrupt to or from the emulator system and is defined as input/output by way of IEEE standard 1149.1 scan system. When $\overline{\text{TRST}}$ is driven low, EMU1/$\overline{\text{OFF}}$ is configured as $\overline{\text{OFF}}$. The EMU1/$\overline{\text{OFF}}$ signal, when active low, puts all output drivers into the high-impedance state. Note that $\overline{\text{OFF}}$ is used exclusively for testing and emulation purposes (not for multiprocessing applications). Therefore, for the $\overline{\text{OFF}}$ condition, the following apply: $\overline{\text{TRST}}$ = low, EMU0 = high EMU1/$\overline{\text{OFF}}$ = low

† I = Input, O = Output, Z = High-impedance, S = Supply
‡ These pins have Schmitt trigger inputs.
§ This pin has an internal bus holder controlled by way of the BSCR register.
¶ This pin has an internal pullup resistor.
# This pin has an internal pulldown resistor.

memory

The ’VC5416 device provides both on-chip ROM and RAM memories to aid in system performance and integration.

data memory

The data memory space addresses up to 64K of 16-bit words. The device automatically accesses the on-chip RAM when addressing within its bounds. When an address is generated outside the RAM bounds, the device automatically generates an external access.

The advantages of operating from on-chip memory are as follows:

- Higher performance because no wait states are required
- Higher performance because of better flow within the pipeline of the central arithmetic logic unit (CALU)
- Lower cost than external memory
- Lower power than external memory

The advantage of operating from off-chip memory is the ability to access a larger address space.

program memory

Software can configure their memory cells to reside inside or outside of the program address map. When the cells are mapped into program space, the device automatically accesses them when their addresses are within bounds. When the program-address generation (PAGEN) logic generates an address outside its bounds, the device automatically generates an external access. The advantages of operating from on-chip memory are as follows:

- Higher performance because no wait states are required
- Lower cost than external memory
- Lower power than external memory

The advantage of operating from off-chip memory is the ability to access a larger address space.

extended program memory

The ’VC5416 uses a paged extended memory scheme in program space to allow access of up to 8192K of program memory. In order to implement this scheme, the ’VC5416 includes several features which are also present on ’C548/549/5410:

- Twenty-three address lines, instead of sixteen
- An extra memory-mapped register, the XPC
- Six extra instructions for addressing extended program space

Program memory in the ’VC5416 is organized into 128 pages that are each 64K in length.

The value of the XPC register defines the page selection. This register is memory-mapped into data space to address 001Eh. At a hardware reset, the XPC is initialized to 0.

on-chip ROM with bootloader

The ’VC5416 features a 16K-word × 16-bit on-chip maskable ROM that can only be mapped into program memory space.

Customers can arrange to have the ROM of the ’VC5416 programmed with contents unique to any particular application.

A bootloader is available in the standard ’VC5416 on-chip ROM. This bootloader can be used to automatically transfer user code from an external source to anywhere in the program memory at power up. If MP/$\overline{MC}$ of the device is sampled low during a hardware reset, execution begins at location FF80h of the on-chip ROM. This location contains a branch instruction to the start of the bootloader program. The standard ’VC5416 devices provide different ways to download the code to accomodate various system requirements:

- Parallel from 8-bit or 16-bit-wide EPROM
- Parallel from I/O space, 8-bit or 16-bit mode
- Serial boot from serial ports, 8-bit or 16-bit mode
- Host-port interface boot
- Warm boot

The standard on-chip ROM layout is shown in Table 1.

Table 1. Standard On-Chip ROM Layout†

ADDRESS RANGE	DESCRIPTION
C000h–D4FFh	ROM tables for the GSM EFR speech codec
D500h–D6FFh	256-point complex radix-2 DIT FFT with looped code
D700h–DCFFh	FFT twiddle factors for a 256-point complex radix-2 FFT
DD00h–DEFFh	1024-point complex radix-2 DIT FFT with looped code
DF00h–F7FFh	FFT twiddle factors for a 1024-point complex radix-2 FFT
F800h–FBFFh	Bootloader
FC00h–FCFFh	μ-Law expansion table
FD00h–FDFFh	A-Law expansion table
FE00h–FEFFh	Sine look-up table
FF00h–FF7Fh	Reserved†
FF80h–FFFFh	Interrupt vector table

† In the ’VC5416 ROM, 128 words are reserved for factory device-testing purposes. Application code to be implemented in on-chip ROM must reserve these 128 words at addresses FF00h–FF7Fh in program space.

on-chip RAM

The ’VC5416 device contains 64K-word × 16-bit of on-chip dual-access RAM (DARAM) and 64K-word × 16-bit of on-chip single-access RAM (SARAM).

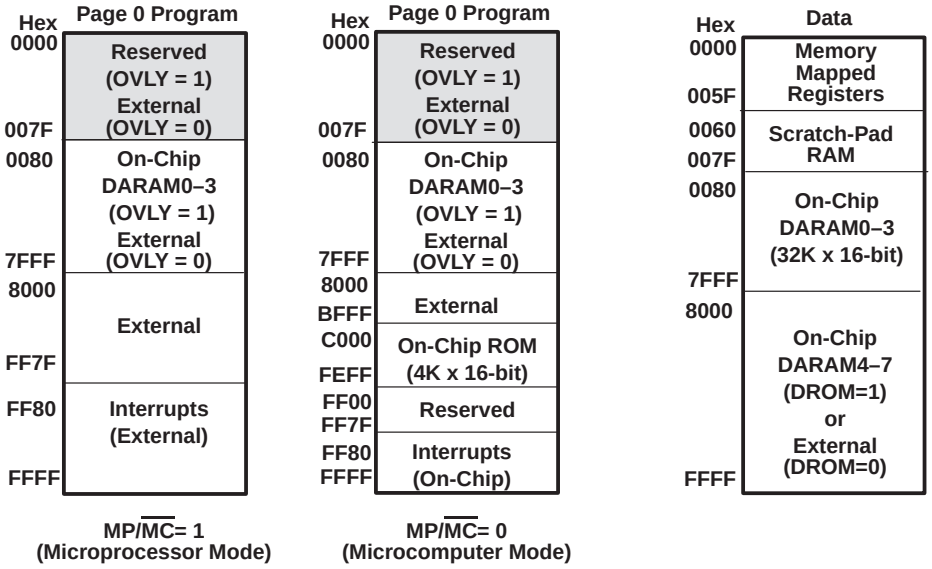
The DARAM is composed of eight blocks of 8K words each. Each block in the DARAM can support two reads in one cycle, or a read and a write in one cycle. Four blocks of DARAM is located in the address range 0080h–7FFFh in data space, and can be mapped into program/data space by setting the OVLY bit to one. The other four blocks of DARAM is located in the address range 18000h–1FFFFh in program space. The DARAM located in the address rage 18000h–1FFFFh in program space can be mapped into data space by setting the DROM bit to one.

The SARAM is composed of eight blocks of 8K words each. Each of these eight blocks is a single-access memory. For example, an instruction word can be fetched from one SARAM block in the same cycle as a data word is written to another SARAM block. The SARAM is located in the address range 28000h–2FFFFh, and 38000h–3FFFFh in program space.

on-chip memory security

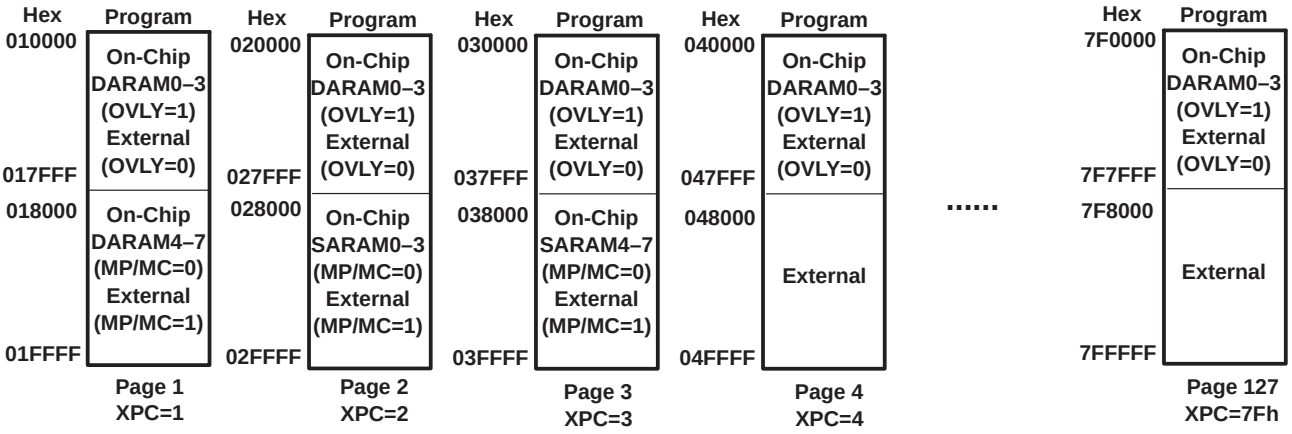
The ’VC5416 device has a maskable option to protect the contents of on-chip memories. When the ROM protect bit is set, no externally originating instruction can access the on-chip memory spaces; HPI writes have no restriction, but HPI reads are restricted to 4000h – 5FFFh.

memory map



Address ranges for on-chip DARAM in data memory are:
DARAM0: 0080h–1FFFh; DARAM1: 2000h–3FFFh
DARAM2: 4000h–5FFFh; DARAM3: 6000h–7FFFh
DARAM4: 8000h–9FFFh; DARAM5: A000h–BFFFh
DARAM6: C000h–DFFFh; DARAM7: E000h–FFFFh

Figure 1. Program and Data Memory Map



Address ranges for on-chip DARAM in program memory are:
DARAM4: 018000h–019FFFh; DARAM5: 01A000h–01BFFFh
DARAM6: 01C000h–01DFFFh; DARAM7: 01E000h–01FFFFh

Address ranges for on-chip SARAM in program memory are:
SARAM0: 028000h–029FFFh; SARAM1: 02A000h–02BFFFh
SARAM2: 02C000h–02DFFFh; SARAM3: 02E000h–02FFFFh
SARAM4: 038000h–039FFFh; SARAM5: 03A000h–03BFFFh
SARAM6: 03C000h–03DFFFh; SARAM7: 03E000h–03FFFFh

Figure 2. Extended Program Memory Map

relocatable interrupt vector table

The reset, interrupt, and trap vectors are addressed in program space. These vectors are soft — meaning that the processor, when taking the trap, loads the program counter (PC) with the trap address and executes the code at the vector location. Four words, either two 1-word instructions or one 2-word instruction, are reserved at each vector location to accommodate a delayed branch instruction which allows branching to the appropriate interrupt service routine without the overhead.

At device reset, the reset, interrupt, and trap vectors are mapped to address FF80h in program space. However, these vectors can be remapped to the beginning of any 128-word page in program space after device reset. This is done by loading the interrupt vector pointer (IPTR) bits in the PMST register with the appropriate 128-word page boundary address. After loading IPTR, any user interrupt or trap vector is mapped to the new 128-word page.

NOTE: The hardware reset ($\overline{RS}$) vector cannot be remapped because the hardware reset loads the IPTR with 1s. Therefore, the reset vector is always fetched at location FF80h in program space.

on-chip peripherals

The ’VC5416 device has the following peripherals:

- Software-programmable wait-state generator
- Programmable bank-switching
- A host-port interface (HPI8/16)
- Three multichannel buffered serial ports (McBSPs)
- A hardware timer
- A clock generator with a multiple phase-locked loop (PLL)
- Enhanced external parallel interface (XIO2)
- A DMA controller (DMA)

software-programmable wait-state generator

The software wait-state generator of the ’5402 can extend external bus cycles by up to fourteen machine cycles. Devices that require more than fourteen wait states can be interfaced using the hardware READY line. When all external accesses are configured for zero wait states, the internal clocks to the wait-state generator are automatically disabled. Disabling the wait-state generator clocks reduces the power comsumption of the ’5402.

The software wait-state register (SWWSR) controls the operation of the wait-state generator. The 14 LSBs of the SWWSR specify the number of wait states (0 to 7) to be inserted for external memory accesses to five separate address ranges. This allows a different number of wait states for each of the five address ranges. Additionally, the software wait-state multiplier (SWSM) bit of the software wait-state control register (SWCR) defines a multiplication factor of 1 or 2 for the number of wait states. At reset, the wait-state generator is initialized to provide seven wait states on all external memory accesses. The SWWSR bit fields are shown in Figure 3 and described in Table 2.

15	14 – 12	11 – 9	8 – 6	5 – 3	2 – 0
XPA	I/O	Data	Data	Program	Program
R/W-0	R/W-111	R/W-111	R/W-111	R/W-111	R/W-111

LEGEND: R=Read, W=Write, 0=Value after reset

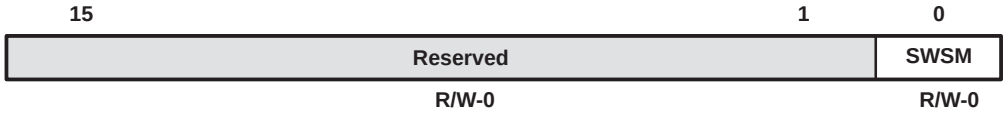
Figure 3. Software Wait-State Register (SWWSR) [Memory-Mapped Register (MMR) Address 0028h]

software-programmable wait-state generator (continued)

Table 2. Software Wait-State Register (SWWSR) Bit Fields

BIT NO.	BIT NAME	RESET VALUE	FUNCTION
15	XPA	0	Extended program address control bit. XPA is used in conjunction with the program space fields (bits 0 through 5) to select the address range for program space wait states.
14–12	I/O	1	I/O space. The field value (0–7) corresponds to the base number of wait states for I/O space accesses within addresses 0000–FFFFh. The SWSM bit of the SWCR defines a multiplication factor of 1 or 2 for the base number of wait states.
11–9	Data	1	Upper data space. The field value (0–7) corresponds to the base number of wait states for external data space accesses within addresses 8000–FFFFh. The SWSM bit of the SWCR defines a multiplication factor of 1 or 2 for the base number of wait states.
8–6	Data	1	Lower data space. The field value (0–7) corresponds to the base number of wait states for external data space accesses within addresses 0000–7FFFh. The SWSM bit of the SWCR defines a multiplication factor of 1 or 2 for the base number of wait states.
5–3	Program	1	Upper program space. The field value (0–7) corresponds to the base number of wait states for external program space accesses within the following addresses: ❑ XPA = 0: x8000 – xFFFFh ❑ XPA = 1: The upper program space bit field has no effect on wait states. The SWSM bit of the SWCR defines a multiplication factor of 1 or 2 for the base number of wait states.
2–0	Program	1	Program space. The field value (0–7) corresponds to the base number of wait states for external program space accesses within the following addresses: ❑ XPA = 0: x0000–x7FFFh ❑ XPA = 1: 00000–FFFFFh The SWSM bit of the SWCR defines a multiplication factor of 1 or 2 for the base number of wait states.

The software wait-state multiplier bit of the software wait-state control register (SWCR) is used to extend the base number of wait states selected by the SWWSR. The SWCR bit fields are shown in Figure 4 and described in Table 3.



LEGEND: R = Read, W = Write

Figure 4. Software Wait-State Control Register (SWCR) [MMR Address 002Bh]

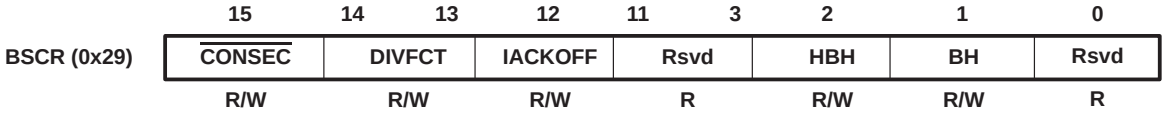
Table 3. Software Wait-State Control Register (SWCR) Bit Fields

PIN NO.	PIN NAME	RESET VALUE	FUNCTION
15–1	Reserved	0	These bits are reserved and are unaffected by writes.
0	SWSM	0	Software wait-state multiplier. Used to multiply the number of wait states defined in the SWWSR by a factor of 1 or 2. ❑ SWSM = 0: wait-state base values are unchanged (multiplied by 1). ❑ SWSM = 1: wait-state base values are mulitplied by 2 for a maximum of 14 wait states.

programmable bank-switching

Programmable bank-switching logic allows the ’VC5416 to switch between external memory banks without requiring external wait states for memories that need additional time to turn off. The bank-switching logic automatically inserts one cycle when accesses cross a 32K-word memory-bank boundary inside program or data space.

Bank-switching is defined by the bank-switching control register (BSCR), which is memory-mapped at address 0029h. The bit fields of the BSCR are shown in Figure 5 and are described in Table 4.



R = Read, W = Write

Figure 5. Bank-Switching Control Register (BSCR)

Table 4. Bank-Switching Control Register Fields

BIT	NAME	RESET VALUE	FUNCTION
15	$\overline{\text{CONSEC}}$†	1	Consecutive bank-switching. Specifies the bank-switching mode. $\overline{\text{CONSEC}}$ = 0 Bank-switching on 32K bank boundaries only. This bit is cleared if fast access is desired for continuous memory reads (i.e., no starting and trailing cycles between read cycles). $\overline{\text{CONSEC}}$ = 1 Consecutive bank switches on external memory reads. Each read cycle consists of 3 cycles: starting cycle, read cycle, and trailing cycle.
13–14	DIVFCT	11	CLKOUT output divide factor. The CLKOUT output is driven by an on-chip source having a frequency equal to 1/(DIVFCT+1) of the DSP clock. DIVFCT = 00 CLKOUT is not divided. DIVFCT = 01 CLKOUT is divided by 2 from the DSP clock. DIVFCT = 10 CLKOUT is divided by 3 from the DSP clock. DIVFCT = 11 CLKOUT is divided by 4 from the DSP clock (default value following reset).
12	IACKOFF	1	$\overline{\text{IACK}}$ signal output off. Controls the output of the $\overline{\text{IACK}}$ signal. IACKOFF is set to 1 at reset. IACKOFF = 0 The $\overline{\text{IACK}}$ signal output off function is disabled. IACKOFF = 1 The $\overline{\text{IACK}}$ signal output off function is enabled.
11–3	Rsvd	–	Reserved
2	HBH	0	HPI bus holder. Controls the HPI bus holder. HBH is cleared to 0 at reset. HBH = 0 The bus holder is disabled except when HPI16=1. HBH = 1 The bus holder is enabled. When not driven, the HPI data bus, HD[7:0] is held in the previous logic level.
1	BH	0	Bus holder. Controls the bus holder. BH is cleared to 0 at reset. BH = 0 The bus holder is disabled. BH = 1 The bus holder is enabled. When not driven, the data bus, D[15:0] is held in the previous logic level.
0	Rsvd	–	Reserved

† For additional information, see the “enhanced external parallel interface (XIO2)” section of this document.

programmable bank-switching (continued)

The ’VC5416 has an internal register that holds the MSB of the last address used for a read or write operation in program or data space. In the non-consecutive bank switches ($\overline{\text{CONSEC}}$ = 0), if the MSB of the address used for the current read does not match that contained in this internal register, the $\overline{\text{MSTRB}}$ (memory strobe) signal is not asserted for one CLKOUT cycle. During this extra cycle, the address bus switches to the new address. The contents of the internal register are replaced with the MSB for the read of the current address. If the MSB of the address used for the current read matches the bits in the register, a normal read cycle occurs.

In non-consecutive bank switches ($\overline{\text{CONSEC}}$ = 0), if repeated reads are performed from the same memory bank, no extra cycles are inserted. When a read is performed from a different memory bank, memory conflicts are avoided by inserting an extra cycle. For more information, see the “enhanced external parallel interface (XIO2)” section of this document.

The bank-switching mechanism automatically inserts one extra cycle in the following cases:

- A memory read followed by another memory read from a different memory bank.
- A program-memory read followed by a data-memory read.
- A data-memory read followed by a program-memory read.
- A program-memory read followed by another program-memory read from a different page.

bus holders

The ’5416 has two bus holder control bits, BH (BSCR[1]) and HBH (BSCR[2]), to control the bus keepers of the address bus (A[17–0]), data bus (D[15–0]) and the HPI data bus (HD[7–0]). The bus keeper enabling/disabling is described in Table 5.

Table 5. Bus Holder Control Bits

HPI16 pin	BH	HBH	D[15–0]	A[17–0]	HD[7–0]
0	0	0	OFF	OFF	OFF
0	0	1	OFF	OFF	ON
0	1	0	ON	OFF	OFF
0	1	1	ON	OFF	ON
1	0	0	OFF	OFF	ON
1	0	1	OFF	ON	ON
1	1	0	ON	OFF	ON
1	1	1	ON	ON	ON

parallel I/O ports

The ’5416 has a total of 64K I/O ports. These ports can be addressed by the PORTR instruction or the PORTW instruction. The $\overline{\text{IS}}$ signal indicates a read/write operation through an I/O port. The ’VC5416 can interface easily with external devices through the I/O ports while requiring minimal off-chip address-decoding circuits.

enhanced 8-/16-bit host-port interface (HPI8/16)

The ’5416 host-port interface, also referred to as the HPI8/16, is an enhanced version of the standard 8-bit HPI found on earlier ’54x DSPs (’542, ’545, ’548, and ’549). The ’5416 HPI can be used to interface to an 8-bit or 16-bit host. When the address and data buses for external I/O is not used (to interface to external devices in program/data/IO spaces), the ’5416 HPI can be configured as an HPI16 to interface to a 16-bit host. This configuration can be accomplished by connecting the HPI16 pin to logic “1”.

enhanced 8-/16-bit host-port interface (HPI8/16) (continued)

When the HPI16 pin is connected to a logic “0”, the ’5416 HPI is configured as an HPI8. The HPI8 is an 8-bit parallel port for interprocessor communication. The features of the HPI8 include:

Standard features:

- Sequential transfers (with autoincrement) or random-access transfers
- Host interrupt and ’54x interrupt capability
- Multiple data strobes and control pins for interface flexibility

The HPI8 interface consists of an 8-bit bidirectional data bus and various control signals. Sixteen-bit transfers are accomplished in two parts with the HBIL input designating high or low byte. The host communicates with the HPI8 through three dedicated registers — HPI address register (HPIA), HPI data register (HPID), and an HPI control register (HPIC). The HPIA and HPID registers are only accessible by the host, and the HPIC register is accessible by both the host and the ’5416.

Enhanced features:

- Access to entire on-chip RAM through DMA bus
- Capability to continue transferring during emulation stop

The HPI16 is an enhanced 16-bit version of the ’C54x 8-bit host-port interface (HPI8). The HPI16 is designed to allow a 16-bit host to access the DSP on-chip memory, with the host acting as the master of the interface. Some of the features of the HPI16 include:

- 16-bit bidirectional data bus
- Multiple data strobes and control signals to allow glueless interfacing to a variety of hosts
- Multiplexed and nonmultiplexed address/data modes
- 18-bit address bus used in nonmultiplexed mode to allow access to all internal memory (including internal extended address pages)
- 18-bit address register used in multiplexed mode. Includes address autoincrement feature for faster accesses to sequential addresses interface to on-chip DMA module to allow access to entire internal memory space
- HRDY signal to hold off host accesses due to DMA latency
- Control register available in *multiplexed* mode only. Accessible by either host or DSP to provide host/DSP interrupts, extended addressing, and data prefetch capability
- The HPI16 acts as a slave to a 16-bit host processor and allows access to the on-chip memory of the DSP.

NOTE: Only the nonmultiplexed mode is supported when the ’5416 HPI is configured as a HPI16 (see Figure 6).

The ’5416 HPI functions as a slave and enables the host processor to access the on-chip memory. A major enhancement to the ’5416 HPI over previous versions is that it allows host access to the entire on-chip memory range of the DSP. The host and the DSP both have access to the on-chip RAM at all times and host accesses are always synchronized to the DSP clock. If the host and the DSP contend for access to the same location, the host has priority, and the DSP waits for one cycle. Note that since host accesses are always synchronized to the ’5416 clock, an active input clock (CLKIN) is required for HPI accesses during IDLE states, and host accesses are not allowed while the ’5416 reset pin is asserted.

HPI nonmultiplexed mode

In *nonmultiplexed* mode, a host with separate address/data buses can access the HPI16 data register (HPID) via the HD 16-bit bidirectional data bus, and the address register (HPIA) via the 23-bit HA address bus. The host initiates the access with the strobe signals ($\overline{\text{HDS1}}$, $\overline{\text{HDS2}}$, $\overline{\text{HCS}}$) and controls the direction of the access with the HR/$\overline{\text{W}}$ signal. The HPI16 can stall host accesses via the HRDY signal. Note that the HPIC register is not available in *nonmultiplexed* mode since there are no HCNTL signals available. All host accesses initiate a DMA read or write access. Figure 6 shows a block diagram of the HPI16 in *nonmultiplexed* mode.

HPI nonmultiplexed mode (continued)

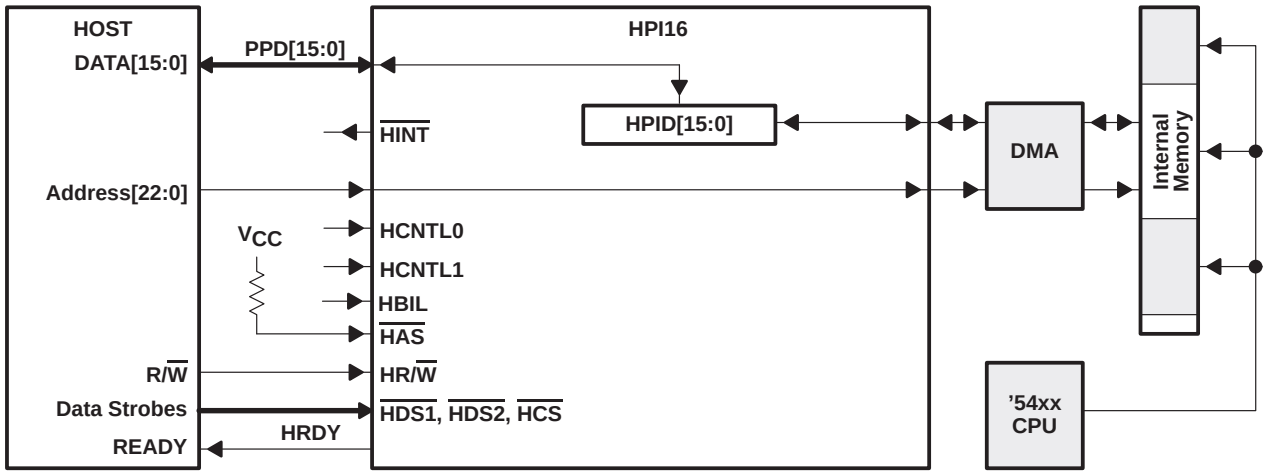


Figure 6. Host-Port Interface — Nonmultiplexed Mode

HPI nonmultiplexed mode (continued)

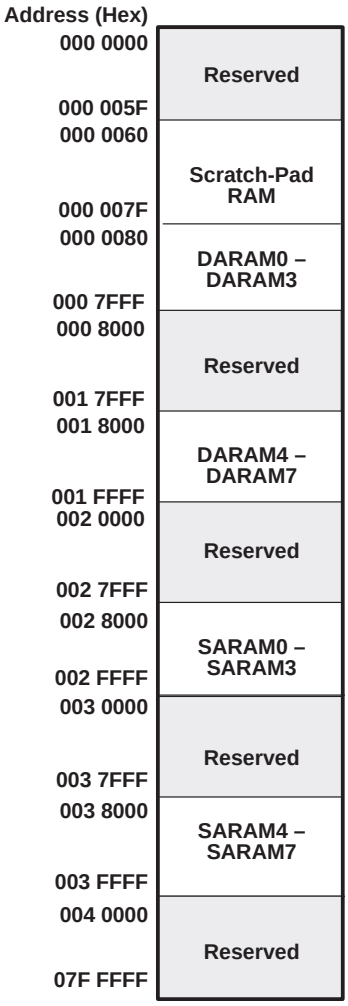

Figure 7. HPI8 Memory Map

multichannel buffered serial ports (McBSPs)

The ’VC5416 device provides three high-speed, full-duplex, multichannel buffered serial ports that allow direct interface to other ’C54x/’LC54x devices, codecs, and other devices in a system. The McBSPs are based on the standard serial-port interface found on other ’54x devices. Like their predecessors, the McBSPs provide:

- Full-duplex communication
- Double-buffer data registers, which allow a continuous data stream
- Independent framing and clocking for receive and transmit

In addition, the McBSPs have the following capabilities:

- Direct interface to:
  - T1/E1 framers
  - MVIP switching compatible and ST-BUS compliant devices
  - IOM-2 compliant devices
  - AC97-compliant devices
  - IIS-compliant devices
  - Serial peripheral interface
- Multichannel transmit and receive of up to 128 channels
- A wide selection of data sizes, including 8, 12, 16, 20, 24, or 32 bits
- μ-law and A-law companding
- Programmable polarity for both frame synchronization and data clocks
- Programmable internal clock and frame generation

The McBSP consists of a data path and control path. The six pins, BDX, BDR, BFSX, BFSR, BCLKX, and BCLKR, connect the control and data paths to external devices. The implemented pins can be programmed as general-purpose I/O pins if they are not used for serial communication.

The data is communicated to devices interfacing to the McBSP by way of the data transmit (BDX) pin for transmit and the data receive (BDR) pin for receive. The CPU or DMA reads the received data from the data receive register (DRR) and writes the data to be transmitted to the data transmit register (DXR). Data written to the DXR is shifted out to BDX by way of the transmit shift register (XSR). Similarly, receive data on the BDR pin is shifted into the receive shift register (RSR) and copied into the receive buffer register (RBR). RBR is then copied to DRR, which can be read by the CPU or DMA. This allows internal data movement and external data communications simultaneously.

Control information in the form of clocking and frame synchronization is communicated by way of BCLKX, BCLKR, BFSX, and BFSR. The device communicates to the McBSP by way of 16-bit-wide control registers accessible via the internal peripheral bus.

The control block consists of internal clock generation, frame synchronization signal generation, and their control, and multichannel selection. This control block sends notification of important events to the CPU and DMA by way of two interrupt signals, XINT and RINT, and two event signals, XEVT and REVT.

The on-chip compounding hardware allows compression and expansion of data in either μ-law or A-law format. When compounding is used, transmitted data is encoded according to the specified compounding law and received data is decoded to 2s complement format.

multichannel buffered serial ports (McBSPs) (continued)

The sample rate generator provides the McBSP with several means of selecting clocking and framing for both the receiver and transmitter. Both the receiver and transmitter can select clocking and framing independently.

The McBSP allows the multiple channels to be independently selected for the transmitter and receiver. When multiple channels are selected, each frame represents a time-division multiplexed (TDM) data stream. In using time-division multiplexed data streams, the CPU may only need to process a few of them. Thus, to save memory and bus bandwidth, multichannel selection allows independent enabling of particular channels for transmission and reception. All 128 channels in a bit stream consisting of a maximum of 128 channels can be enabled.

R						R/W	R/W		R/W		R			R/W	

LEGEND: R = Read, W = Write

Figure 8. Multichannel Control Registers (MCR1 and MCR2)

The ’5416 McBSP has two working modes:

- In the first mode, when (R/X)MCME = 0, it is comparable with the McBSPs used in the ’5410 where the normal 32-channel selection is enabled (default).
- In the second mode, when (R/X)MCME = 1, it has 128 channel selection capability. Multichannel control register Bit 9, (R/X)MCME, is used as the 128-channel selection enable bit. Once (R/X)MCME = 1, twelve new registers ((R/X)CER0 – (R/X)CER11) are used to enable the 128 channel selection

The clock stop mode (CLKSTP) in the McBSP provides compatibility with the serial port interface protocol. Clock stop mode works with only single-phase frames and one word per frame. The word sizes supported by the McBSP are programmable for 8-, 12-, 16-, 20-, 24-, or 32-bit operation. When the McBSP is configured to operate in SPI mode, both the transmitter and the receiver operate together as a master or as a slave.

Although the BCLKS pin is not available on the ’5416 PGE and GGU packages, the ’5416 is capable of synchronization to external clock sources. BCLKX or BCLKR can be used by the sample rate generator for external synchronization. The sample rate clock mode extended (SCLKME) bit field is located in the PCR to accommodate this option.

15	14	13	12	11	10	9	8

RW	RW	RW	RW	RW	RW	RW	RW

Legend: R = Read, W = Write

Figure 9. Pin Control Register (PCR)

multichannel buffered serial ports (McBSPs) (continued)

The selection of sample rate input clock is made by the combination of the CLKSM (bit 13 in SRGR2) bit value and the SCLKME bit value as shown in Table 6.

Table 6. Sample Rate Input Clock Selection

SCLKME	CLKSM	SAMPLE RATE CLOCK MODE
0	0	Reserved (CLKS pin unavailable)
0	1	CPU clock
1	0	BCLKR
1	1	BCLKX

When the SCLKME bit is cleared to 0, the CLKSM bit is used, as before, to select either the CPU clock or the CLKS pin (not bonded out on the ’5416 device package) as the sample rate input clock. Setting the SCLKME bit to 1, enables the CLKSM bit to select between the BCLKR pin or BCLKX pin for the sample rate input clock.

When either the BCLKR or CLKX is configured this way, the output buffer for the selected pin is automatically disabled. For example, with SCLKME=1 and CLKSM=0, the BCLKR pin is configured as the input of the sample rate generator. Both the transmitter and receiver circuits can be synchronized to the sample rate generator output by setting the CLKXM and CLKRM bits of the pin configuration register (PCR) to 1. Note that the sample rate generator output will only be driven on the BCLKX pin since the BCLKR output buffer is automatically disabled.

The McBSP is fully static and operates at arbitrary low clock frequencies. For maximum operating frequency, refer to the timing section.

hardware timer

The ’VC5416 device features a 16-bit timing circuit with a 4-bit prescaler. The timer counter is decremented by one every CLKOUT cycle. Each time the counter decrements to 0, a timer interrupt is generated. The timer can be stopped, restarted, reset, or disabled by specific status bits.

clock generator

The clock generator provides clocks to the ’VC5416 device, and consists of an internal oscillator and a phase-locked loop (PLL) circuit. The clock generator requires a reference clock input, which can be provided by using a crystal resonator with the internal oscillator, or from an external clock source. The reference clock input is then divided by two (DIV mode) to generate clocks for the ’VC5416 device, or the PLL circuit can be used (PLL mode) to generate the device clock by multiplying the reference clock frequency by a scale factor, allowing use of a clock source with a lower frequency than that of the CPU.The PLL is an adaptive circuit that, once synchronized, locks onto and tracks an input clock signal.

When the PLL is initially started, it enters a transitional mode during which the PLL acquires lock with the input signal. Once the PLL is locked, it continues to track and maintain synchronization with the input signal. Then, other internal clock circuitry allows the synthesis of new clock frequencies for use as master clock for the ’VC5416 device.

This clock generator allows system designers to select the clock source. The sources that drive the clock generator are:

- A crystal resonator circuit. The crystal resonator circuit is connected across the X1 and X2/CLKIN pins of the ’VC5416 to enable the internal oscillator.
- An external clock. The external clock source is directly connected to the X2/CLKIN pin, and X1 is left unconnected.

clock generator (continued)

The software-programmable PLL features a high level of flexibility, and includes a clock scaler that provides various clock multiplier ratios, capability to directly enable and disable the PLL, and a PLL lock timer that can be used to delay switching to PLL clocking mode of the device until lock is achieved.Devices that have a built-in software-programmable PLL can be configured in one of two clock modes:

- PLL mode. The input clock (X2/CLKIN) is multiplied by 1 of 31 possible ratios.
- DIV (divider) mode. The input clock is divided by 2 or 4. Note that when DIV mode is used, the PLL can be completely disabled in order to minimize power dissipation.

The software-programmable PLL is controlled using the 16-bit memory-mapped (address 0058h) clock mode register (CLKMD). The CLKMD register is used to define the clock configuration of the PLL clock module. Note that upon reset, the CLKMD register is initialized with a predetermined value dependent only upon the state of the CLKMD1 – CLKMD3 pins. For more programming information, see the *TMS320C54x DSP Reference Set, Volume 1: CPU and Peripherals* (literature number SPRU131). The CLKMD pin configured clock options are shown in Table 7.

Table 7. Clock Mode Settings at Reset

CLKMD1	CLKMD2	CLKMD3	CLKMD RESET VALUE	CLOCK MODE†
0	0	0	0000h	1/2 (PLL and Oscillator disabled)
0	0	1	9007h	PLL x 10 (Oscillator enabled)
0	1	0	4007h	PLL x 5 (Oscillator enabled)
1	0	0	1007h	PLL x 2(Oscillator enabled)
1	1	0	F007h	PLL x 1 (Oscillator enabled)
1	1	1	0000h	1/2 (PLL disabled, Oscillator enabled)
1	0	1	F000h	1/4 (PLL disabled, Oscillator enabled)
0	1	1	—	Reserved (Bypass mode)

† The external CLKMD1–CLKMD3 pins are sampled to determine the desired clock generation mode while $\overline{RS}$ is low. Following reset, the clock generation mode can be reconfigured by writing to the internal clock mode register in software. However, the oscillator enable/disable selection is performed independently of the state of $\overline{RS}$; therefore, if CLKMD1–CLKMD3 are changed following reset, the oscillator enable/disable selection may change, but other aspects of the clock generation mode will not.

enhanced external parallel interface (XIO2)

The ’VC5416 external interface has been redesigned to include several improvements, including: simplification of the bus sequence, more immunity to bus contention when transitioning between read and write operations, the ability for external memory access to the DMA controller, and optimization of the power-down modes.

The bus sequence on the ’VC5416 still maintains all of the same interface signals as on previous ’54x devices, but the signal sequence has been simplified. Most external accesses now require 3 cycles composed of a leading cycle, an active (read or write) cycle, and a trailing cycle. The leading and trailing cycles provide additional immunity against bus contention when switching between read operations and write operations. To maintain high-speed read access, a consecutive read mode that performs single-cycle reads as on previous ’54x devices is available.

Figure 10 shows the bus sequence for three cases: all I/O reads, memory reads in nonconsecutive mode, or single memory reads in consecutive mode. The accesses shown in Figure 10 always require 3 CLKOUT cycles to complete.

enhanced external parallel interface (XIO2) (continued)

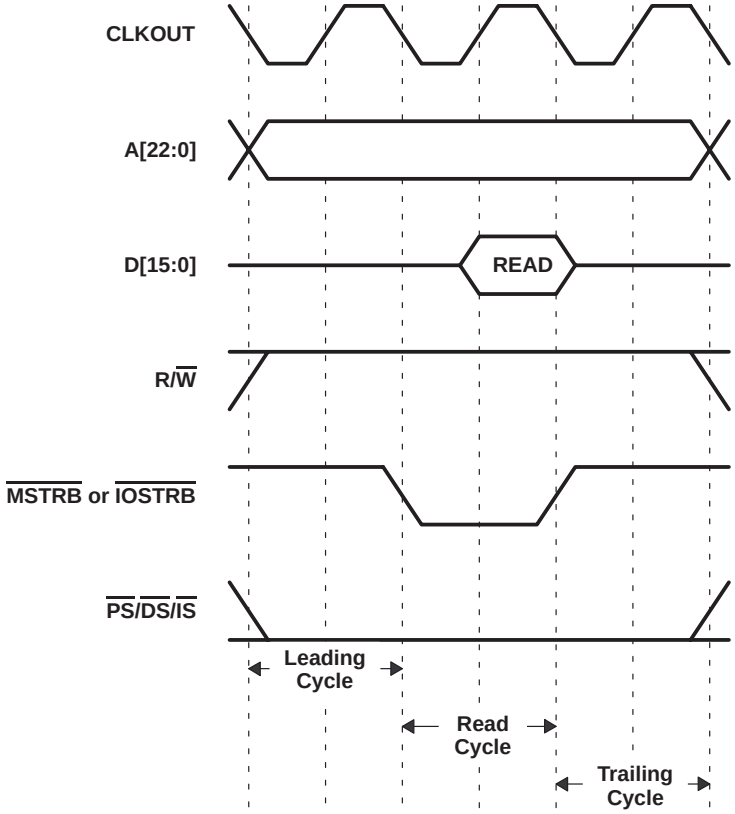

Figure 10. Nonconsecutive Memory Read and I/O Read Bus Sequence

enhanced external parallel interface (XIO2) (continued)

Figure 11 shows the bus sequence for repeated memory reads in consecutive mode. The accesses shown in Figure 11 require (2+n) CLKOUT cycles to complete, where n is the number of consecutive reads performed.

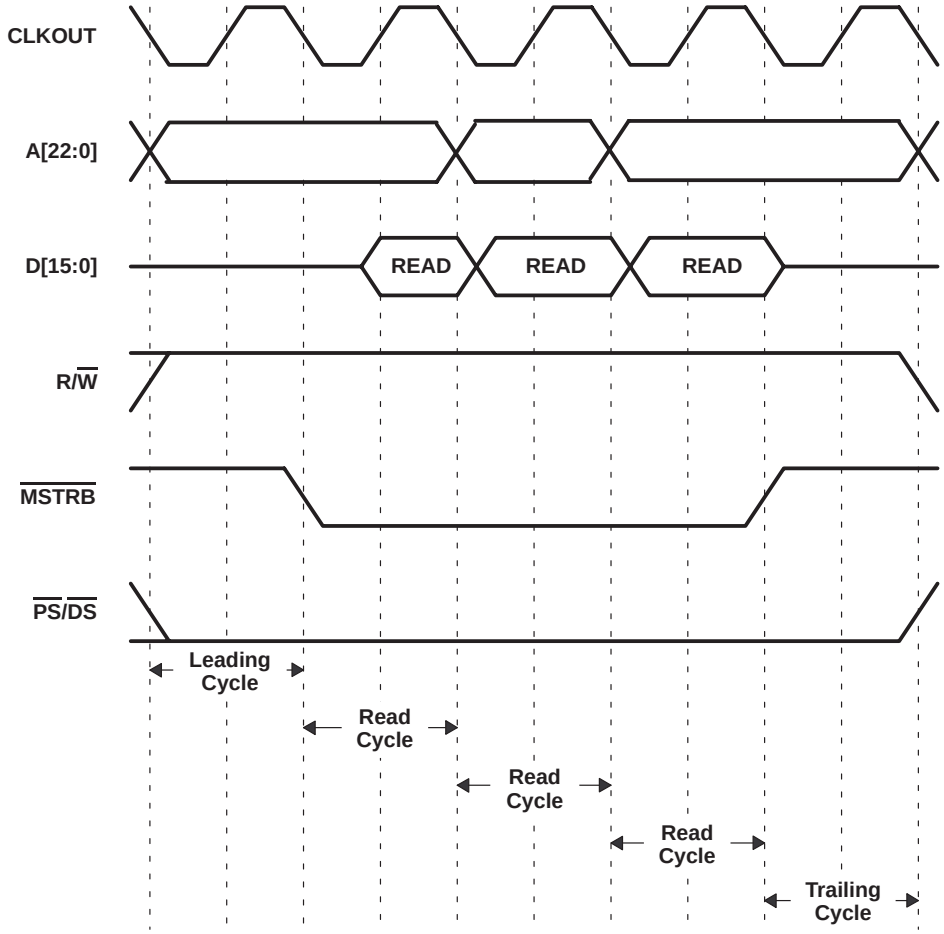

Figure 11. Consecutive Memory Read Bus Sequence (n = 3 reads)

enhanced external parallel interface (XIO2) (continued)

Figure 12 shows the bus sequence for all memory writes and I/O writes. The accesses shown in Figure 12 always require 3 CLKOUT cycles to complete.

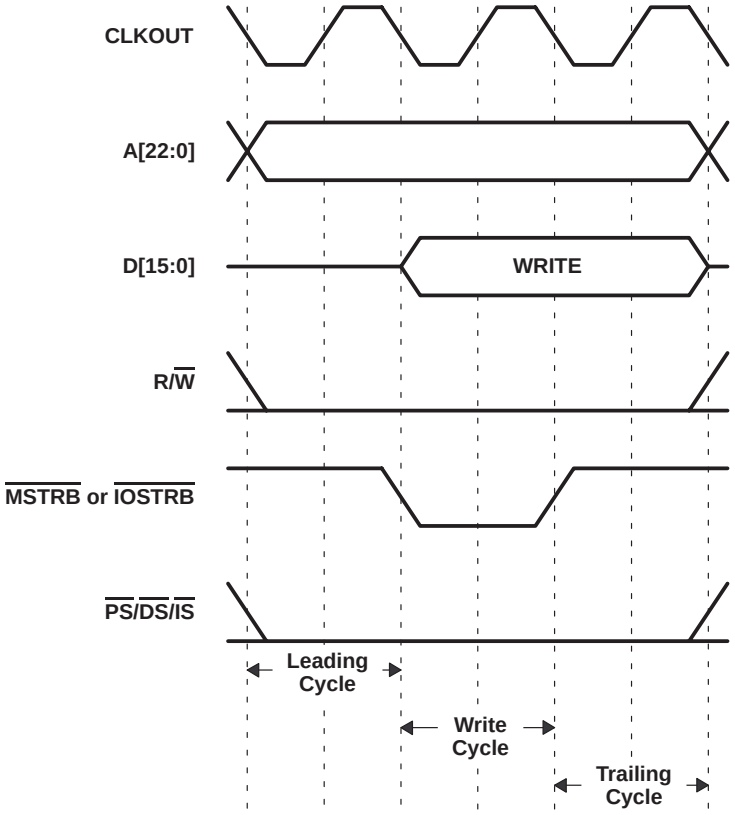

Figure 12. Memory Write and I/O Write Bus Sequence

The enhanced interface also provides the ability for DMA transfers to extend to external memory. For more information on DMA capability, see the DMA sections that follow.

The enhanced interface improves the low-power performance already present on the ’C5000 family by switching off the internal clocks to the interface when it is not being used. This power-saving feature is automatic, requires no software setup, and causes no latency in the operation of the interface.

Additional features integrated in the enhanced interface are the ability to automatically insert bank-switching cycles when crossing 32K memory boundaries (see the “programmable bank-switching” section), the ability to program up to 14 wait states through software (see the “software-programmable wait-state generator” section), and the ability to divide down CLKOUT by a factor of 1, 2, 3, or 4. Dividing down CLKOUT provides an alternative to wait states when interfacing to slower external memory or peripheral devices. While inserting wait states extends the bus sequence during read or write accesses, it does not slow down the bus signal sequences at the beginning and the end of the access. Dividing down CLKOUT provides a method of slowing the entire bus sequence when necessary. The CLKOUT divide-down factor is controlled through the DIVFCT field in the bank-switching control register (BSCR).

DMA controller

The ’VC5416 direct memory access (DMA) controller transfers data between points in the memory map without intervention by the CPU. The DMA allows movements of data to and from internal program/data memory, internal peripherals (such as the McBSPs), or external memory devices to occur in the background of CPU operation. The DMA has six independent programmable channels, allowing six different contexts for DMA operation.

features

The DMA has the following features:

- The DMA operates independently of the CPU.
- The DMA has six channels. The DMA can keep track of the contexts of six independent block transfers.
- The DMA has higher priority than the CPU for both internal and external accesses.
- Each channel has independently programmable priorities.
- Each channel’s source and destination address registers can have configurable indexes through memory on each read and write transfer, respectively. The address may remain constant, be post-incremented, be post-decremented, or be adjusted by a programmable value.
- Each read or write internal transfer may be initialized by selected events.
- On completion of a half- or entire-block transfer, each DMA channel may send an interrupt to the CPU.
- The DMA can perform double-word internal transfers (a 32-bit transfer of two 16-bit words).

DMA external access

The ’5416 DMA supports external accesses to extended program, extended data, and extended I/O memory. These overlay pages are only visible to the DMA controller. A maximum of two DMA channels can be used for external memory accesses. The DMA external accesses require 8-cycles for external writes and 11-cycle minimums for external reads assuming the XIO02 is in consecutive mode (CONSEC=1), wait state is set to two, and CLKOUT is not divided (DIVFCT=00).

The control of the bus is arbitrated between the CPU and the DMA. While the DMA or CPU is in control of the external bus the other will be held–off via wait states until the current transfer is complete. The DMA takes precedence over XIO requests.

- Only two channels are available for external accesses. (One for external reads/one for external writes.)
- Single-word (16-bit) transfers are supported for external accesses.
- The DMA does not support transfers from peripherals to external memory.
- The DMA does not support transfers from external memory to the peripherals.
- The DMA does not support external to external transfers.

To allow the DMA access to extended data pages, the SLAXS and DLAXs bits are added to the DMMCRn register.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Figure 13. DMA Transfer Mode Control Register Bit Layout

DMA external access (continued)

These new bit fields were created to allow the user to define the space select for the DMA (internal/external). Also a new extended destination data page (XDSTDP[6:0], subaddress 029h) and extended source data page (XSRCDP[6:0], subaddress 028h) have been created.

DLAXS(DMMCRn[5]) Destination	0 = No external access (default internal)
	1 = External access
SLAXS(DMMCRn[11]) Source	0 = No external access (default internal)
	1 = External access

Table 8. DMD Section of the DMMCRn Register

DMD	DESTINATION SPACE
00	PS
01	DS
10	I/O
11	Reserved

For the CPU external access, software can configure the memory cells to reside inside or outside the program address map. When the cells are mapped into program space, the device automatically accesses them when their addresses are within bounds. When the address generation logic generates an address outside its bounds, the device automatically generates an external access.

Two new registers are added to the ’5416 DMA to support DMA accesses to/from DMA extended data memory, page 1 to page 127.

- The DMA extended source data page register (XSRCDP[6:0]) is located at subbank address 028h.
- The DMA extended destination data page register (XDSTDP[6:0]) is located at subbank address 029h.

DMA memory map

The DMA memory map, see Figure 14, allows the DMA transfer to be unaffected by the status of the MP/$\overline{\text{MC}}$, DROM, and OVLY bits.

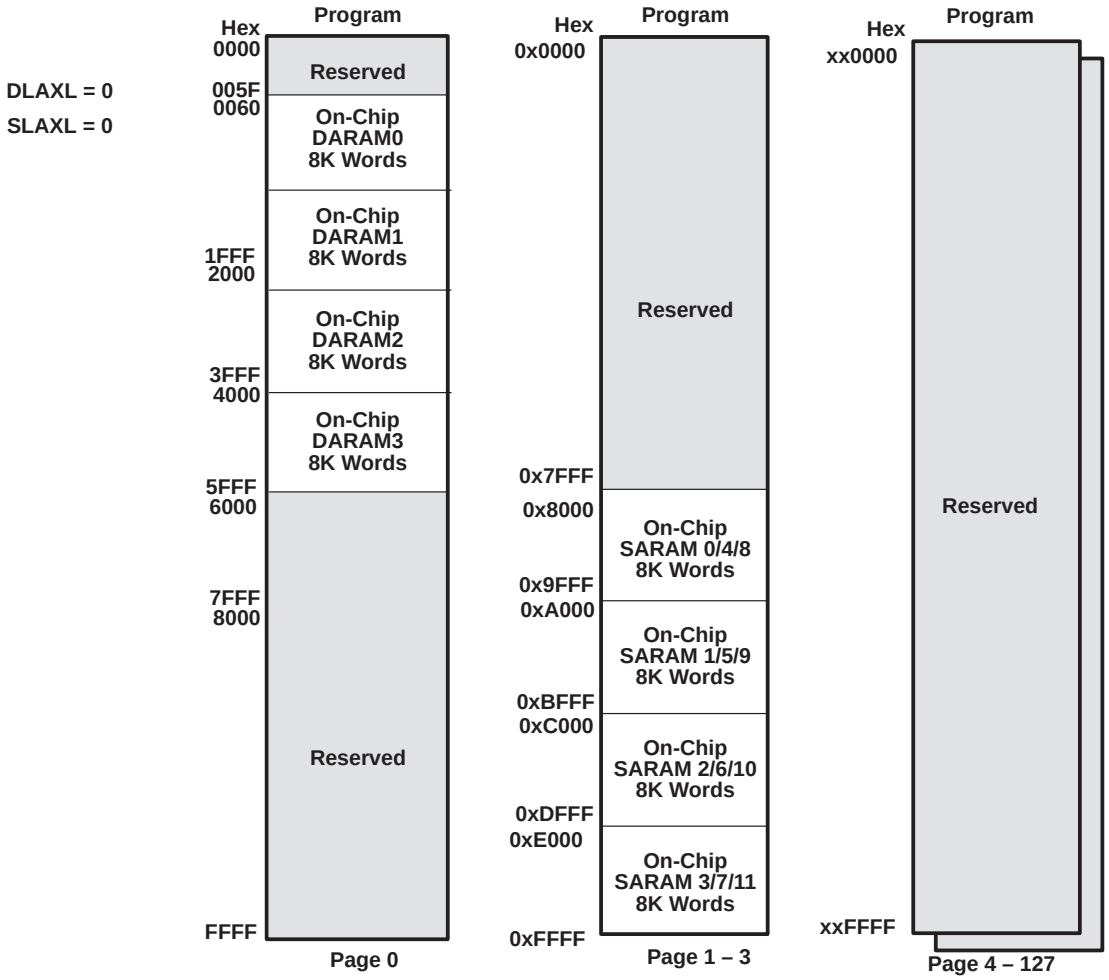

Figure 14. On-Chip DMA Memory Map for Program Space (DLAXL = 0 and SLAXL = 0)

DMA memory map (continued)

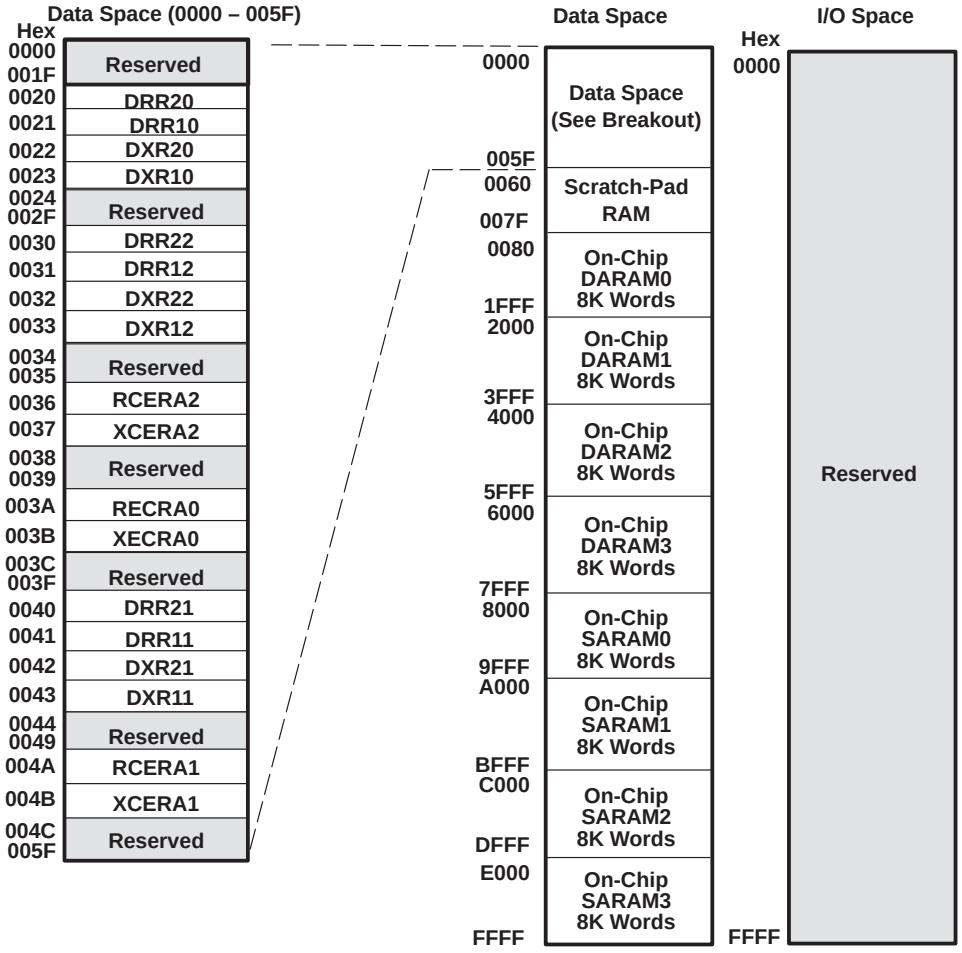

Figure 15. On-Chip DMA Memory Map for Data and IO Space (DLAXL = 0 and SLAXL = 0)

DMA priority level

Each DMA channel can be independently assigned high- or low-priority relative to each other. Multiple DMA channels that are assigned to the same priority level are handled in a round-robin manner.

DMA source/destination address modification

The DMA provides flexible address-indexing modes for easy implementation of data management schemes such as autobuffering and circular buffers. Source and destination addresses can be indexed separately and can be post-incremented, post-decremented, or post-incremented with a specified index offset.

DMA in autoinitialization mode

The DMA can automatically reinitialize itself after completion of a block transfer. Some of the DMA registers can be preloaded for the next block transfer through the DMA global reload registers (DMGSA, DMGDA, DMGCR, and DMGFR). Autoinitialization allows:

- Continuous operation: Normally, the CPU would have to reinitialize the DMA immediately after the completion of the current block transfers, but with the global reload registers, it can reinitialize these values for the next block transfer any time after the current block transfer begins.
- Repetitive operation: The CPU does not preload the global reload register with new values for each block transfer but only loads them on the first block transfer.

DMA in autoinitialization mode (continued)

The ’5416 DMA has been enhanced to expand the DMA global reload register sets. Each DMA channel now has its own DMA global reload register set. For example, the DMA global reload register set for channel 0 has DMGSA0, DMGDA0, DMGCR0, and DMGFR0 while DMA channel 1 has DMGSA1, DMGDA1, DMGCR1, and DMGFR1, etc.

To utilize the additional DMA global reload registers, the AUTOIX bit is added to the DMPREC register as shown in Figure 16.

AUTOIX	DMA GLOBAL RELOAD REGISTER USAGE IN AUTO INIT MODE
0 (default)	All DMA channels use DMGSA0, DMGDA0, DMGCR0 and DMGFR0
1	Each DMA channel uses its own set of global reload registers

DMA transfer counting

The DMA channel element count register (DMCTRx) and the frame count register (DMFRCx) contain bit fields that represent the number of frames and the number of elements per frame to be transferred.

- Frame count. This 8-bit value defines the total number of frames in the block transfer. The maximum number of frames per block transfer is 128 (FRAME COUNT= 0ffh). The counter is decremented upon the last read transfer in a frame transfer. Once the last frame is transferred, the selected 8-bit counter is reloaded with the DMA global frame reload register (DMGFR) if the AUTOINIT bit is set to 1. A frame count of 0 (default value) means the block transfer contains a single frame.
- Element count. This 16-bit value defines the number of elements per frame. This counter is decremented after the read transfer of each element. The maximum number of elements per frame is 65536 (DMCTRn = 0ffffh). In autoinitialization mode, once the last frame is transferred, the counter is reloaded with the DMA global count reload register (DMGCR).

DMA transfer in double-word mode

Double-word mode allows the DMA to transfer 32-bit words in any index mode. In double-word mode, two consecutive 16-bit transfers are initiated and the source and destination addresses are automatically updated following each transfer. In this mode, each 32-bit word is considered to be one element.

DMA channel index registers

The particular DMA channel index register is selected by way of the SIND and DIND fields in the DMA mode control register (DMMCRx). Unlike basic address adjustment, in conjunction with the frame index DMFRI0 and DMFRI1, the DMA allows different adjustment amounts depending on whether or not the element transfer is the last in the current frame. The normal adjustment value (element index) is contained in the element index registers DMIDX0 and DMIDX1. The adjustment value (frame index) for the end of the frame, is determined by the selected DMA frame index register, either DMFRI0 or DMFRI1.

The element index and the frame index affect address adjustment as follows:

- Element index: For all except the last transfer in the frame, the element index determines the amount to be added to the DMA channel for the source/destination address register (DMSRCx/DMDSTx) as selected by the SIND/DIND bits.
- Frame index: If the transfer is the last in a frame, frame index is used for address adjustment as selected by the SIND/DIND bits. This occurs in both single-frame and multi-frame transfers.

DMA interrupts

The ability of the DMA to interrupt the CPU based on the status of the data transfer is configurable and is determined by the IMOD and DINM bits in the DMA mode control register (DMMCRn). The available modes are shown in Table 10.

Table 10. DMA Interrupts

MODE	DINM	IMOD	INTERRUPT
ABU (non-decrement)	1	0	At full buffer only
ABU (non-decrement)	1	1	At half buffer and full buffer
Multiframe	1	0	At block transfer complete (DMCTRn = DMSEFCn[7:0] = 0)
Multiframe	1	1	At end of frame and end of block (DMCTRn = 0)
Either	0	X	No interrupt generated
Either	0	X	No interrupt generated

DMA controller synchronization events

The transfers associated with each DMA channel can be synchronized to one of several events. The DSYN bit field of the DMSEFCn register selects the synchronization event for a channel. The list of possible events and the DSYN values are shown in Table 11.

Table 11. DMA Synchronization Events

DSYN VALUE	DMA SYNCHRONIZATION EVENT
0000b	No synchronization used
0001b	McBSP0 receive event
0010b	McBSP0 transmit event
0011b	McBSP2 receive event
0100b	McBSP2 transmit event

1100b	McBSP1 trasnmit event – ABIS mode
1101b	Timer interrupt event
1110b	External interrupt 3
1111b	Reserved

DMA channel interrupt selection

The DMA controller can generate a CPU interrupt for each of the six channels. However, due to a limit on the number of internal CPU interrupt inputs, channels 0, 1, 2, and 3 are multiplexed with other interrupt sources. DMA channels 0, 1, 2, and 3 share an interrupt line with the receive and transmit portions of the McBSP. When the ’5409 is reset, the interrupts from these three DMA channels are deselected. The INTSEL bit field in the DMPREC register can be used to select these interrupts, as shown in Table 12.

Table 12. DMA Channel Interrupt Selection

INTSEL Value	IMR/IFR[6]	IMR/IFR[7]	IMR/IFR[10]	IMR/IFR[11]
00b (reset)	BRINT2	BXINT2	BRINT1	BXINT1
01b	BRINT2	BXINT2	DMAC2	DMAC3
10b	DMAC0	DMAC1	DMAC2	DMAC3
11b	Reserved			

general-purpose I/O pins

In addition to the standard $\overline{\text{BIO}}$ and XF pins, the ’5416 has pins that can be configured for general-purpose I/O. These pins are:

- 18 McBSP pins — BCLKX0/1/2, BCLKR0/1/2, BDR0/1/2, BFSX0/1/2, BFSR0/1/2, BDX01/2
- 8 HPI data pins—HD0–HD7

The general-purpose I/O function of these pins is only available when the primary pin function is not required.

McBSP pins as general-purpose I/O

When the receive or transmit portion of a McBSP is in reset, its pins can be configured as general-purpose inputs or outputs. For more details on this feature, refer to the McBSP specification.

HPI data pins as general-purpose I/O

The 8-bit bidirectional data bus of the HPI can be used as general-purpose input/output (GPIO) pins when the HPI is disabled (HPIENA = 0) or when the HPI is used in HPI16 mode (HPI16 = 1). Two memory-mapped registers are used to control the GPIO function of the HPI data pins—the general-purpose I/O control register (GPIOCR) and the general-purpose I/O status register (GPIOSR). The GPIOCR is shown in Figure 17.

PRODUCT PREVIEW

memory-mapped registers

The ’VC5416 has 27 memory-mapped CPU registers, which are mapped in data memory space address 0h to 1Fh. Each ’VC5416 device also has a set of memory-mapped registers associated with peripherals. Table 13 gives a list of CPU memory-mapped registers (MMRs) available on ’VC5416. Table 14 shows additional peripheral MMRs associated with the ’VC5416.

McBSP control registers and subaddresses

The control registers for the multichannel buffered serial port (McBSP) are accessed using the subbank addressing scheme. This allows a set or subbank of registers to be accessed through a single memory location. The McBSP subbank address register (SPSA) is used as a pointer to select a particular register within the subbank. The McBSP data register (SPSDx) is used to access (read or write) the selected register. Table 15 shows the McBSP control registers and their corresponding subaddresses.

DMA subbank addressed registers

The direct memory access (DMA) controller has several control registers associated with it. The main control register (DMPREC) is a standard memory-mapped register. However, the other registers are accessed using the subbank addressing scheme. This allows a set or subbank of registers to be accessed through a single memory location. The DMA subbank address (DMSA) register is used as a pointer to select a particular register within the subbank, while the DMA subbank data (DMSD) register or the DMA subbank data register with autoincrement (DMSDI) is used to access (read or write) the selected register.

When the DMSDI register is used to access the subbank, the subbank address is automatically postincremented so that a subsequent access affects the next register within the subbank. This autoincrement feature is intended for efficient, successive accesses to several control registers. If the autoincrement feature is not required, the DMSDN register should be used to access the subbank. Table 16 shows the DMA controller subbank addressed registers and their corresponding subaddresses.

DMA subbank addressed registers (continued)

documentation support

Extensive documentation supports all TMS320 family generations of devices from product announcement through applications development. The following types of documentation are available to support the design and use of the ’C5000 family of DSPs:

- *TMS320C5000 DSP Family Functional Overview* (literature number SPRU307)
- Device-specific data sheets (such as this document)
- Complete user’s guides
- Development support tools
- Hardware and software application reports

The five-volume *TMS320C54x DSP Reference Set* (literature number SPRU210) consists of:

- *Volume 1: CPU and Peripherals* (literature number SPRU131)
- *Volume 2: Mnemonic Instruction Set* (literature number SPRU172)
- *Volume 3: Algebraic Instruction Set* (literature number SPRU179)
- *Volume 4: Applications Guide* (literature number SPRU173)
- *Volume 5: Enhanced Peripherals* (literature number SPRU302)

The reference set describes in detail the ’54x TMS320 products currently available and the hardware and software applications, including algorithms, for fixed-point TMS320 devices.

For general background information on DSPs and Texas Instruments (TI™) devices, see the three-volume publication *Digital Signal Processing Applications with the TMS320 Family* (literature numbers SPRA012, SPRA016, and SPRA017).

A series of DSP textbooks is published by Prentice-Hall and John Wiley & Sons to support digital signal processing research and education. The TMS320 newsletter, *Details on Signal Processing*, is published quarterly and distributed to update TMS320 customers on product information.

Information regarding TI DSP products is also available on the Worldwide Web at *http://www.ti.com* uniform resource locator (URL).

absolute maximum ratings over specified temperature range (unless otherwise noted)†

Supply voltage I/O range, DV_{DD}‡ . . . . . –0.3 V to 4.0 V
Supply voltage core range, CV_{DD}‡ . . . . . –0.3 V to 2.0 V
Input voltage range . . . . . –0.3 V to 4.5 V
Output voltage range . . . . . –0.3 V to 4.5 V
Operating case temperature range, T_C . . . . . –40°C to 100°C
Storage temperature range, T_{stg} . . . . . –55°C to 150°C

† Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
‡ All voltage values are with respect to DV_{SS}.

Figure 21. 3.3-V Test Load Circuit

internal oscillator with external crystal

The internal oscillator is enabled by selecting the appropriate clock mode at reset (this is device-dependent; see **clock generator** section) and connecting a crystal or ceramic resonator across X1 and X2/CLKIN. The CPU clock frequency is one-half, one-fourth or a multiple of the oscillator frequency. The multiply ratio is determined by the bit settings in the CLKMD register.

The crystal should be in fundamental-mode operation, and parallel resonant, with an effective series resistance of 30 Ω and power dissipation of 1 mW. The connection of the required circuit, consisting of the crystal and two load capacitors, is shown in Figure 22. The load capacitors, C_1 and C_2, should be chosen such that the equation below is satisfied. C_L in the equation is the load specified for the crystal.

$$C_L = \frac{C_1 C_2}{(C_1 + C_2)}$$

		MIN	NOM	MAX	
f_X	Input clock frequency	10†		20‡	MHz

† This device utilizes a fully static design and therefore can operate with $t_{c(CI)}$ approaching ∞. The device is characterized at frequencies approaching 0 Hz

‡ It is recommended that the PLL multiply by N clocking option be used for maximum frequency operation.

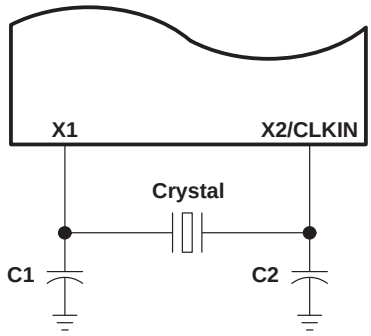

Figure 22. Internal Divide-by-Two Clock Option With External Crystal

PRODUCT PREVIEW

divide-by-two and divide-by-four clock options

The frequency of the reference clock provided at the X2/CLKIN pin can be divided by a factor of two or four to generate the internal machine cycle. The selection of the clock mode is described in the clock generator section.

When an external clock source is used, the frequency injected must conform to specifications listed in the timing requirements table.

An external frequency source can be used by applying an input clock to X2/CLKIN with X1 left unconnected.

Table 18 shows the configuration options for the CLKMD pins that generate the external divide-by-2 or by 4 clock option.

Table 18. Clock Mode Pin Settings for the Divide-By-2 and By Divide-by-4 Clock Options

CLKMD1	CLKMD2	CLKMD3	CLOCK MODE
0	0	0	1/2, PLL disabled, OSC disabled
1	0	4	1/4, PLL disabled, OSC enabled
1	1	1	1/2, PLL disabled, OSC enabled

switching characteristics over recommended operating conditions [H = 0.5$t_{c(CO)}$] (see Figure 22, Figure 23, and the recommended operating conditions table)

Figure 23. External Divide-by-Two Clock Timing

PRODUCT PREVIEW

multiply-by-N clock option – PLL enabled

The frequency of the reference clock provided at the X2/CLKIN pin can be multiplied by a factor of N to generate the internal machine cycle. The selection of the clock mode and the value of N is described in the clock generator section. Following reset, the software PLL can be programmed for the desired multiplication factor. Refer to the *TMS320C54x DSP CPU and Peripherals Reference Set*, Volume 1 (literature number SPRU131) for detailed information on programming the PLL.

When an external clock source is used, the external frequency injected must conform to specifications listed in the timing requirements table.

$t_{su(MPMC)}$	Setup time, MP/$\overline{\text{MC}}$ before CLKOUT low	5		ns

† The external interrupts ($\overline{\text{INT0}}$–$\overline{\text{INT3}}$, $\overline{\text{NMI}}$) are synchronized to the core CPU by way of a two-flip-flop synchronizer that samples these inputs with consecutive falling edges of CLKOUT. The input to the interrupt pins is required to represent a 1–0–0 sequence at the timing that is corresponding to three CLKOUTs sampling sequence.

‡ If the PLL mode is selected, then at power-on sequence, or at wakeup from IDLE3, $\overline{\text{RS}}$ must be held low for at least 50 μs to ensure synchronization and lock-in of the PLL.

§ Note that $\overline{\text{RS}}$ may cause a change in clock frequency, therefore changing the value of H.

¶ The diagram assumes clock mode is divide-by-2 and the CLKOUT divide factor is set to no-divide mode (DIVFCT=00 field in the BSCR).

$t_{d(COH-HYH)}$	Delay time, CLKOUT high to HRDY high			6	ns
$t_{d(COH-HTX)}$	Delay time, CLKOUT high to $\overline{HINT}$ change			6	ns
$t_{d(COH-GPIO)}$	Delay time, CLKOUT high to HDx output change. HDx is configured as a general-purpose output			5	ns

† DS refers to the logical OR of $\overline{HCS}$, $\overline{HDS1}$, and $\overline{HDS2}$.
‡ HD refers to any of the HPI data bus pins (HD0, HD1, HD2, etc.). HAD stands for HCNTL0, HCNTL1, and HR/$\overline{W}$.
§ DMAC stands for direct memory access controller (DMAC). The HPI8 shares the internal DMA bus with the DMAC, thus HPI8 access times are affected by DMAC activity.
¶ The HRDY output is always high when the $\overline{HCS}$ input is high, regardless of DS timings.
# This timing applies when writing a one to the DSPINT bit or $\overline{HINT}$ bit of the HPIC register. All other writes to the HPIC occur asynchronously, and do not cause HRDY to be deasserted.
‖ P = 0.5 * processor clock

IMPORTANT NOTICE

Texas Instruments and its subsidiaries (TI) reserve the right to make changes to their products or to discontinue any product or service without notice, and advise customers to obtain the latest version of relevant information to verify, before placing orders, that information being relied on is current and complete. All products are sold subject to the terms and conditions of sale supplied at the time of order acknowledgment, including those pertaining to warranty, patent infringement, and limitation of liability.

TI warrants performance of its semiconductor products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are utilized to the extent TI deems necessary to support this warranty. Specific testing of all parameters of each device is not necessarily performed, except those mandated by government requirements.

Customers are responsible for their applications using TI components.

In order to minimize risks associated with the customer's applications, adequate design and operating safeguards must be provided by the customer to minimize inherent or procedural hazards.

TI assumes no liability for applications assistance or customer product design. TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right of TI covering or relating to any combination, machine, or process in which such semiconductor products or services might be or are used. TI's publication of information regarding any third party's products or services does not constitute TI's approval, warranty or endorsement thereof.
