# Ultra－Low－Distortion，＋5V， 400MHz Op Amps with Disable 

## General Description

The MAX4265－MAX4270 ultra－low distortion，voltage－feed－ back op amps are capable of driving a $100 \Omega$ load while maintaining ultra－low distortion over a wide bandwidth． They offer superior spurious－free dynamic range（SFDR） performance：-90 dBc at 5 MHz and -59 dBc at 100 MHz （MAX4269）．Additionally，input voltage noise density is $8 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ while operating from a single +4.5 V to +8.0 V sup－ ply or from dual $\pm 2.25 \mathrm{~V}$ to $\pm 4.0 \mathrm{~V}$ supplies．These features make the MAX4265－MAX4270 ideal for use in high－perfor－ mance communications and signal－processing applica－ tions that require low distortion and wide bandwidth．
The MAX4265 single and MAX4268 dual amplifiers are unity－gain stable．The MAX4266 single and MAX4269 dual amplifiers are compensated for a minimum stable gain of $+2 \mathrm{~V} / \mathrm{V}$ ，while the MAX4267 single and MAX4270 dual amplifiers are compensated for a minimum stable gain of $+5 \mathrm{~V} / \mathrm{V}$ ．
For additional power savings，these amplifiers feature a low－power disable mode that reduces supply current and places the outputs in a high－impedance state．The MAX4265／MAX4266／MAX4267 are available in a space－ saving 8－pin $\mu \mathrm{MAX}$ package，and the MAX4268／ MAX4269／MAX4270 are available in a 16－pin QSOP pack－ age．

Applications
Base－Station Amplifiers
IF Amplifiers
High－Frequency ADC Drivers
High－Speed DAC Buffers
RF Telecom Applications
High－Frequency Signal Processing
－Operates from＋4．5V to＋8．0V
－Superior SFDR with $100 \Omega$ Load
-90 dBc （fc $=5 \mathrm{MHz}$ ）
$-59 \mathrm{dBc}(\mathrm{fc}=100 \mathrm{MHz}$ ）
－35dBm IP3（fc＝20MHz）
－ $8 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ Voltage Noise Density
－100MHz 0．1dB Gain Flatness（MAX4268）
－900V／us Slew Rate
－$\pm 45 m$ A Output Driving Capability
－Disable Mode Places Outputs in High－Impedance State

## ABSOLUTE MAXIMUM RATINGS

Supply Voltage (VCC to $\mathrm{V}_{\mathrm{EE}}$ ) ...................................+8.5V Voltage on Any Other Pin..................(VEE - 0.3V) to (VCC +0.3 V ) Short-Circuit Duration (VOUT to $\mathrm{V}_{\mathrm{CC}}$ or $\mathrm{V}_{\mathrm{EE}}$ )...............Continuous Continuous Power Dissipation $\left(\mathrm{T}_{\mathrm{A}}=+70^{\circ} \mathrm{C}\right)$ 8-Pin $\mu$ MAX (derate $4.10 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ ) .......... 330 mW 16-Pin QSOP (derate $8.33 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ ) $\ldots . . . . .667 \mathrm{~mW}$ 8 -Pin SO (derate $5.9 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ )................ 471 mW 14-Pin SO (derate $8.33 \mathrm{~mW} /{ }^{\circ} \mathrm{C}$ above $+70^{\circ} \mathrm{C}$ )............. 667 mW

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## DC ELECTRICAL CHARACTERISTICS

$\left(\mathrm{V}_{C C}=+5 \mathrm{~V}, \mathrm{~V}_{\mathrm{EE}}=0, R_{\mathrm{L}}=100 \Omega\right.$ to $\mathrm{V}_{\mathrm{CC}} / 2, \mathrm{~V}_{\mathrm{CM}}=\mathrm{V}_{\mathrm{CC}} / 2, \mathrm{~T}_{\mathrm{A}}=\mathrm{T}_{\mathrm{MIN}}$ to $T_{\mathrm{MAX}}$, unless otherwise noted. Typical values are at $\mathrm{T}_{\mathrm{A}}=+25^{\circ} \mathrm{C}$. $)$

## Detailed Description

The MAX4265-MAX4270 family of operational amplifiers features ultra-low distortion and wide bandwidth. Their low distortion and low noise make them ideal for driving high-speed ADCs up to 16 bits in telecommunications applications and high-performance signal processing.
These devices can drive a $100 \Omega$ load and deliver 45 mA while maintaining DC accuracy and AC performance. The input common-mode voltage ranges from (VEE + 1.6 V ) to (VCC - 1.6 V ), while the output typically swings to within 1.1 V of the rails.

## Low Distortion

The MAX4265-MAX4270 use proprietary bipolar technology to achieve minimum distortion in low-voltage systems. This feature is typically available only in dualsupply op amps.
Several factors can affect the noise and distortion that a device contributes to the input signal. The following guidelines explain how various design choices impact the total harmonic distortion (THD):

- Choose the proper feedback-resistor and gain-resistor values for the application. In general, the smaller the closed-loop gain, the smaller the THD generated, especially when driving heavy resistive loads. Largevalue feedback resistors can significantly improve distortion. The MAX4265-MAX4270's THD normally increases at approximately 20 dB per decade at frequencies above 1 MHz ; this is a lower rate than that of comparable dual-supply op amps.
- Operating the device near or above the full-power bandwidth significantly degrades distortion (see the Total Harmonic Distortion vs. Frequency graph in the Typical Operating Characteristics).
- The decompensated devices (MAX4266/MAX4267/ MAX4269/MAX4270) deliver the best distortion performance since they have a slightly higher slew rate and provide a higher amount of loop gain for a given closed-loop gain setting.

## Choosing Resistor Values

## Unity-Gain Configurations

The MAX4265 and MAX4268 are internally compensated for unity gain. When configured for unity gain, they require a small resistor ( $\mathrm{RF}_{\mathrm{F}}$ ) in series with the feedback path (Figure 1). This resistor improves AC response by reducing the Q of the tank circuit, which is formed by parasitic feedback inductance and capacitance.

## Inverting and Noninverting Configurations

 The values of the gain-setting feedback and input resistors are important design considerations. Large resistor values will increase voltage noise and interact with the amplifier's input and PC board capacitance to generate undesirable poles and zeros, which can decrease bandwidth or cause oscillations. For example, a noninverting gain of $+2 \mathrm{~V} / \mathrm{V}$ (Figure 1) using $\mathrm{R}_{\mathrm{F}}=\mathrm{R}_{\mathrm{G}}=1 \mathrm{k} \Omega$ combined with 2 pF of input capacitance and 0.5 pF of board capacitance will cause a feedback pole at 128 MHz . If this pole is within the anticipated amplifier bandwidth, it will jeopardize stability. Reducing the $1 \mathrm{k} \Omega$ resistors to $100 \Omega$ extends the pole frequency to 1.28 GHz , but could limit output swing by adding $200 \Omega$ in parallel with the amplifier's load. Clearly, the selection of resistor values must be tailored to the specific application.
## Distortion Considerations

The MAX4265-MAX4270 are ultra-low-distortion, highbandwidth op amps. Output distortion will degrade as the total load resistance seen by the amplifier decreases. To minimize distortion, keep the input and gain-setting resistor values relatively large. A $500 \Omega$ feedback resistor combined with an appropriate input resistor to set the gain will provide excellent AC performance without significantly increasing distortion.

## Noise Considerations

The amplifier's input-referred noise-voltage density is dominated by flicker noise at lower frequencies and by thermal noise at higher frequencies. Because the thermal noise contribution is affected by the parallel combination of the feedback resistive network, those resistor values should be reduced in cases where the system bandwidth is large and thermal noise is dominant. This noise-contribution factor decreases, however, with increasing gain settings. For example, the input noise voltage density at the op amp input with a gain of $+10 \mathrm{~V} / \mathrm{V}$ using $\mathrm{RF}_{\mathrm{F}}=100 \mathrm{k} \Omega$ and $\mathrm{R}_{\mathrm{G}}=11 \mathrm{k} \Omega$ is $e_{\mathrm{n}}=$ $18 \mathrm{nV} / \sqrt{\mathrm{Hz}}$. The input noise can be reduced to $8 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ by choosing $\mathrm{RF}_{\mathrm{F}}=1 \mathrm{k} \Omega, \mathrm{R}_{\mathrm{G}}=110 \Omega$.

## Driving Capacitive Loads

The MAX4265-MAX4270 are not designed to drive highly reactive loads. Stability is maintained with loads up to 15 pF with less than 2 dB peaking in the frequency response. To drive higher capacitive loads, place a small isolation resistor in series between the amplifier's output and the capacitive load (Figure 1). This resistor improves the amplifier's phase margin by isolating the capacitor from the op amp's output.
To ensure a load capacitance that limits peaking to less than 2 dB , select a resistance value from Figure 2. For example, if the capacitive load is 100 pF , the corresponding isolation resistor is $6 \Omega$ (MAX4266/MAX4269). Figures 3 and 4 show the peaking that occurs in the frequency response with and without an isolation resistor.
Coaxial cable and other transmission lines are easily driven when terminated at both ends with their characteristic impedance. When driving back-terminated transmission lines, the capacitive load of the transmission line is essentially eliminated.

## ADC Input Buffer

Input buffer amplifiers can be a source of significant errors in high-speed ADC applications. The input buffer is usually required to rapidly charge and discharge the ADC's input, which is often capacitive (see Driving Capacitive Loads). In addition, since a high-speed ADC's input impedance often changes very rapidly dur-
ing the conversion cycle, measurement accuracy must
*OPTIONAL, USED TO MINIMIZE PEAKING FOR CL> 15pF
Figure 1. Noninverting Configuration

# Ultra-Low-Distortion, +5V, 400MHz Op Amps with Disable 

be maintained using an amplifier with very low output impedance at high frequencies. The combination of high speed, fast slew rate, low noise, and a low and stable distortion overload makes the MAX4265MAX4270 ideally suited for use as buffer amplifiers in high-speed ADC applications.

Low-Power Disable Mode The MAX4265-MAX4270 feature an active-low disable mode that can be used to save power and place the outputs in a high-impedance state. Drive DISABLE_ with logic levels, or connect DISABLE_ to VCC for normal operation. In the dual versions (MAX4268/ MAX4269/ MAX4270), each individual op amp is disabled separately, allowing the devices to be used in a multiplex configuration. The supply current in low-power mode is reduced to 1.6 mA per amplifier. Enable time is typically 100ns, and disable time is typically $750 \mu \mathrm{~s}$.

Figure 4b. MAX4269 Small-Signal Gain vs. Frequency With Isolation Resistor

Power Supplies, Bypassing, and Layout The MAX4265-MAX4270 operate from a single +4.5 V to +8.0 V supply or in a dual-supply configuration.
When operating with a single supply, connect the $\mathrm{V}_{\mathrm{EE}}$ pins directly to the ground plane. Bypass $V_{C c}$ to ground with ceramic chip capacitors. Due to the MAX4265-MAX4270s' wide bandwidth, use a 1 nF capacitor in parallel with a $0.1 \mu \mathrm{~F}$ to $1 \mu \mathrm{~F}$ capacitor. If the device is located more than 10 cm from the power supply, adding a larger bulk capacitor will improve performance.
When operating with dual supplies, ensure that the total voltage across the device ( $\mathrm{VCC}_{C}$ to $\mathrm{V}_{\mathrm{EE}}$ ) does not exceed +8 V . Therefore, supplies of $\pm 2.5 \mathrm{~V}, \pm 3.3 \mathrm{~V}$, and asymmetrical supplies are possible. For example, operation with $\mathrm{V}_{\mathrm{CC}}=+5 \mathrm{~V}$ and $\mathrm{V}_{\mathrm{EE}}=-3 \mathrm{~V}$ provides sufficient voltage swing for the negative pulses found in video signals. When operating with dual supplies, the $V_{C C}$ pins and the VEE pins should be bypassed using the same guidelines stated in the paragraph above.

Figure 4c. MAX4270 Small-Signal Gain vs. Frequency With Isolation Resistor

Because the MAX4265-MAX4270 have high bandwidth, circuit layout becomes critical. A solid ground plane provides a low-inductance path for high-speed transient currents. Use multiple vias to the ground plane for each bypass capacitor. If $\mathrm{V}_{\mathrm{EE}}$ is connected to ground, use multiple vias here, too. Avoid sharing ground vias with other signals to reduce crosstalk between circuit sections.
Avoid stray capacitance at the op amp's inverting inputs. Stray capacitance, in conjunction with the feedback resistance, forms an additional pole in the circuit's transfer function, with its associate phase shift. Minimizing the trace lengths connected to the inverting input helps minimize stray capacitance.
