LTC1992-5

Gain of 5 Fully Differential Input/Output Amplifier/Driver

September 2003

FEATURES

- **Differential Inputs**
- **Differential Outputs**
- **Fixed Gain of 5 ± 0.3% (Max) Gain Error from −40°C to 85°C**
- **C_{LOAD} Stable from 0 to 10,000pF**
- **Adjustable Output Common Mode Voltage**
- **Output Common Mode Level Independent of Input Common Mode Level**
- Low Supply Current 1.2mA (Max over Temperature)
- High Output Current 10mA (Min over Temperature)
- Rail-to-Rail Output Swing
- Specified on a Single 2.7V to ±5V Supply
- DC Offset Voltage <2.5mV (Max)
- 8-Lead MSOP Package

APPLICATIONS

- Differential Driver/Receiver
- Differential Amplification
- Single-Ended to Differential Conversion
- Level Shifting

DESCRIPTION

The LTC®1992-5 is a fully differential amplifier with a fixed gain of 5. The LTC1992-5 has a separate internal common mode feedback path for better common mode noise rejection, outstanding output gain and phase balancing and reduced second order harmonics. The V_{OCM} pin sets the output common mode level independent of the input common mode level. This feature makes level shifting of signals easy. The integrated precision gain setting resistors ensure gain accuracy without external components.
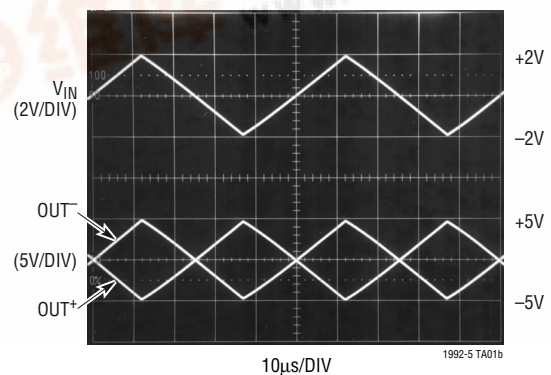

The differential inputs operate with signals ranging from rail-to-rail with a common mode level from the negative supply up to 1.3V from the positive supply. The differential input DC offset is typically 250μV. The rail-to-rail outputs sink and source 10mA. The LTC1992-5 is stable for all capacitive loads up to 10,000pF.

The LTC1992-5 can be used in single-supply applications with supply voltages as low as 2.7V. It can also be used with dual supplies up to ±5V. The LTC1992-5 is available in an 8 pin MSOP package.

LT, LTC and LT are registered trademarks of Linear Technology Corporation.

TYPICAL APPLICATION
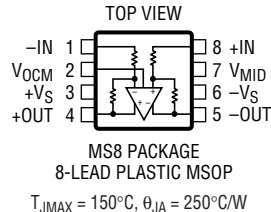

Single-Ended to Differential Conversion

Note 1: Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.

Note 2: Output load is connected to the midpoint of the $+V_S$ and $−V_S$ potentials. Measurement is taken single-ended, one output loaded at a time.

Note 3: A heat sink may be required to keep the junction temperature below the absolute maximum when the output is shorted indefinitely.

Note 4: Slew Rate is measured single-ended. The numbers listed are also single-ended and the differential slew rate would double the listed numbers.

Note 5: The LTC1992-5CMS8, LTC1992-5IMS8 and LTC1992-5HMS8 are guaranteed functional over the extended operating temperature range of −40°C to 125°C.

Note 6: The LTC1992-5CMS8 is guaranteed to meet the specified performance limits over the 0°C to 70°C temperature range and designed, characterized and expected to meet the specified performance from −40°C to 85°C but is not tested or QA sampled at these temperatures. LTC1992-5IMS8 is guaranteed to meet specified performance limits over the −40°C to 85°C temperature range. The LTC1992-5HMS8 is guaranteed to meet the specified performance limits over the −40°C to 125°C temperature range.

Note 7: Differential Offset Voltage, Differential Offset Voltage Drift, CMRR and PSRR are referred to the internal amplifier's input to allow for direct comparison with discrete amplifiers. The LTC1992-5 is an inverting topology with a gain of five. The output referred offset is six times the amplifiers input offset.

LTC1992-5

PIN FUNCTIONS

–IN, +IN (Pins 1,8): Inverting and Noninverting Inputs of the Amplifier. These pins are connected to on-chip gain setting resistors. The input resistors are nominally 30k.
V_{OCM} (Pin 2): Output Common Mode Voltage Set Pin. The voltage on this pin sets the output signal's common voltage level. The output common mode level is set independent of the input common mode level. This is a high impedance input and must be connected to a known and controlled voltage. It must never be left floating.

$+V_S$, $–V_S$ (Pins 3, 6): The $+V_S$ and $–V_S$ power supply pins should be bypassed with 0.1µF capacitors to an adequate analog ground or ground plane. The bypass capacitors should be located as closely as possible to the supply pins

+OUT, –OUT (Pins 4,5): The Positive and Negative Outputs of the Amplifier. These rail-to-rail outputs are designed to drive capacitive loads up to 10,000 pF.

V_{MID} (Pin 7): Mid-Supply Reference. This pin is connected to an on-chip resistive voltage divider (two 200k ±25% resistors) to provide a mid-supply reference. This provides a convenient way to set the output common mode voltage level at half-supply. If used for this purpose, the pin should be bypassed with a 0.1µF capacitor to ground and connected to V_{OCM} (Pin 2). If this reference voltage is not used, leave the pin floating.
