

BIPOLAR ANALOG INTEGRATED CIRCUIT μ PC1028H

FM IF AMPLIFIER WITH DIFFERENTIAL PEAK DETECTOR SILICON BIPOLAR MONOLITHIC INTEGRATED CIRCUIT

DESCRIPTION

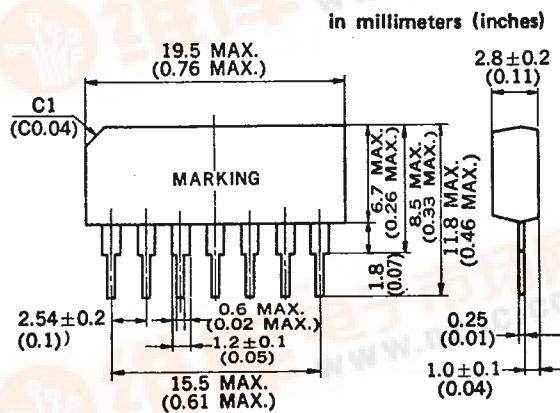

The μ PC1028H is a silicon monolithic integrated circuit intended for an FM IF amplifier with a differential peak detector.

The device contains a three-stage direct coupled differential amplifier, a low pass filter, and a differential peak detector.

The differential peak detector has such feature as simplifying external circuits and components compared with a ratio detector.

The μ PC1028H is packaged in a plastic single in-line package (SIP) for easy mounting on a printed circuit board.

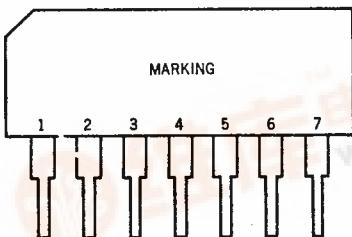

PACKAGE DIMENSIONS

FEATURES

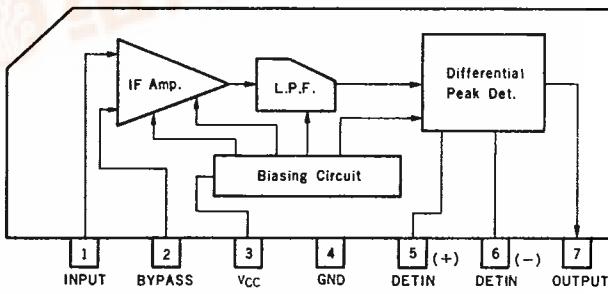

- Few external components required.
- Only one coil necessary in detector circuit, all tuning performed with the coil.
- Low distortion: T.H.D. = 0.3 % TYP. at 100 % modulation.
- SIP assures easy mounting on a printed circuit board.

TEMPERATURE**DETECTOR COIL TUNING PROCEDURE**

1. In the test circuit, the signal generator SG is connected to the input terminal pin 1, and the AF voltmeter and the total harmonic distortion meter are connected to the output terminal pin 7.
 2. The SG is set at $f = 10.7 \text{ MHz}$, $f_{MOD} = 400 \text{ Hz}$, $\Delta f = \pm 22.5 \text{ kHz}$ and the input level to the device under test should be $200 \mu\text{V}$.
 3. After the procedure of 1 and 2, the detector coil is adjusted so that the output level as indicated by the AF voltmeter is maintained the maximum value.
 4. Then the detector coil is finely adjusted so that the total harmonic distortion is obtained the minimum value.
 5. After the setting of 1 mV input level, the procedure of 3 and 4 are repeated.
- (By the tuning at $200 \mu\text{V}$ and 1 mV input level, the device provides the most stable characteristic from weak to strong input signal level.)
