

LT1113

## Dual Low Noise, Precision, JFET Input Op Amps

### FEATURES

- 100% Tested Low Voltage Noise  $6\text{nV}/\sqrt{\text{Hz}}$  Max
- S8 Package Standard Pinout
- Voltage Gain 1.2 Million Min
- Offset Voltage  $1.5\text{mV}$  Max
- Offset Voltage Drift  $15\mu\text{V}/^\circ\text{C}$  Max
- Input Bias Current, Warm Up  $450\text{pA}$  Max
- Gain-Bandwidth Product  $6.3\text{MHz}$  Typ
- Guaranteed Specifications with  $\pm 5\text{V}$  Supplies
- Guaranteed Matching Specifications

### APPLICATIONS

- Photocurrent Amplifiers
- Hydrophone Amplifiers
- High Sensitivity Piezoelectric Accelerometers
- Low Voltage and Current Noise Instrumentation Amplifier Front Ends
- Two and Three Op Amp Instrumentation Amplifiers
- Active Filters

### DESCRIPTION

The LT1113 achieves a new standard of excellence in noise performance for a dual JFET op amp. The  $4.5\text{nV}/\sqrt{\text{Hz}}$   $1\text{kHz}$  noise combined with low current noise and picoampere bias currents makes the LT1113 an ideal choice for amplifying low level signals from high impedance capacitive transducers.

The LT1113 is unconditionally stable for gains of 1 or more, even with load capacitances up to  $1000\text{pF}$ . Other key features are  $0.4\text{mV}$   $V_{OS}$ , voltage gain of 4 million. Each individual amplifier is 100% tested for voltage noise, slew rate, and gain-bandwidth.

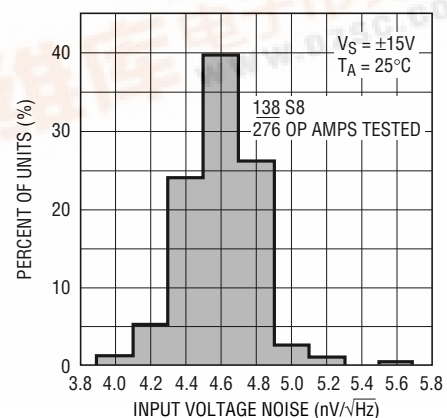

The design of the LT1113 has been optimized to achieve true precision performance with an industry standard pinout in the S8 package. A set of specifications are provided for  $\pm 5\text{V}$  supplies and a full set of matching specifications are provided to facilitate their use in such matching dependent applications as instrumentation amplifier front ends.

### TYPICAL APPLICATION

Low Noise Hydrophone Amplifier with DC Servo

1kHz Input Noise Voltage Distribution

DC OUTPUT  $\leq 2.5\text{mV}$  FOR  $T_A < 70^\circ\text{C}$   
 OUTPUT VOLTAGE NOISE =  $128\text{nV}/\sqrt{\text{Hz}}$  AT  $1\text{kHz}$  (GAIN = 20)  
 $C_1 \geq C_2 = 100\text{pF}$  TO  $5000\text{pF}$ ;  $R_4C_2 > R_8C_1$ ; \*OPTIONAL

1113 TA01

The ● denotes specifications which apply over the full operating temperature range.

**Note 1:** Typical parameters are defined as the 60% yield of parameter distributions of individual amplifiers, i.e., out of 100 LT1113s (200 op amps) typically 120 op amps will be better than the indicated specification.

**Note 2:** Warmed-up  $I_B$  and  $I_{OS}$  readings are extrapolated to a chip temperature of  $50^\circ C$  from  $25^\circ C$  measurements and  $50^\circ C$  characterization data.

**Note 3:** Current noise is calculated from the formula:

$$i_n = (2qI_B)^{1/2}$$

where  $q = 1.6 \times 10^{-19}$  coulomb. The noise of source resistors up to 200M swamps the contribution of current noise.

**Note 4:** Input voltage range functionality is assured by testing offset voltage at the input voltage range limits to a maximum of 2.3mV (A grade), to 2.8mV (C grade).

**Note 5:** This parameter is not 100% tested.

**Note 6:** Slew rate is measured in  $A_V = -1$ ; input signal is  $\pm 7.5V$ , output measured at  $\pm 2.5V$ .

**Note 7:** The LT1113 is not tested and not quality assurance sampled at  $85^\circ C$  and at  $-40^\circ C$ . These specifications are guaranteed by design, correlation and/or inference from  $-55^\circ C$ ,  $0^\circ C$ ,  $25^\circ C$ ,  $70^\circ C$  and/or  $125^\circ C$  tests.

**Note 8:**  $\Delta CMRR$  and  $\Delta PSRR$  are defined as follows:

- (1) CMRR and PSRR are measured in  $\mu V/V$  on the individual amplifiers.
- (2) The difference is calculated between the matching sides in  $\mu V/V$ .
- (3) The result is converted to dB.

**Note 9:** The LT1113 is measured in an automated tester in less than one second after application of power. Depending on the package used, power dissipation, heat sinking, and air flow conditions, the fully warmed-up chip temperature can be  $10^\circ C$  to  $50^\circ C$  higher than the ambient temperature.

## APPLICATIONS INFORMATION

The LT1113 dual in the plastic and ceramic DIP packages are pin compatible to and directly replace such JFET op amps as the OPA2111 and OPA2604 with improved noise performance. Being the lowest noise dual JFET op amp available to date, the LT1113 can replace many bipolar op amps that are used in amplifying low level signals from high impedance transducers. The best bipolar op amps will eventually loose out to the LT1113 when transducer impedance increases due to higher current noise. The low voltage noise of the LT1113 allows it to surpass every dual and most single JFET op amps available. For the best performance versus area available anywhere, the LT1113 is offered in the narrow S8 surface mount package with standard pinout and no degradation in performance.

The low voltage and current noise offered by the LT1113 makes it useful in a wide range of applications, especially where high impedance, capacitive transducers are used such as hydrophones, precision accelerometers, and photo diodes. The total output noise in such a system is the gain times the RMS sum of the op amp input referred voltage noise, the thermal noise of the transducer, and the op amp bias current noise times the transducer impedance. Figure 1 shows total input voltage noise versus source resistance. In a low source resistance (<5k) application the op amp voltage noise will dominate the total noise.

This means the LT1113 will beat out any dual JFET op amp, only the lowest noise bipolar op amps have the edge (at low source resistances). As the source resistance increases from 5k to 50k, the LT1113 will match the best bipolar op amps for noise performance, since the thermal noise of the transducer ( $4kTR$ ) begins to dominate the total noise. A further increase in source resistance, above 50k, is where the op amp's current noise component ( $2qI_B R_{TRANS}$ ) will eventually dominate the total noise. At these high source resistances, the LT1113 will out perform the lowest noise bipolar op amp due to the inherently low current noise of FET input op amps. Clearly, the LT1113 will extend the range of high impedance transducers that can be used for high signal to noise ratios. This makes the LT1113 the best choice for high impedance, capacitive transducers.

The high input impedance JFET front end makes the LT1113 suitable in applications where very high charge sensitivity is required. Figure 2 illustrates the LT1113 in its inverting and noninverting modes of operation. A charge amplifier is shown in the inverting mode example; here the gain depends on the principal of charge conservation at the input of the LT1113. The charge across the transducer capacitance,  $C_S$ , is transferred to the feedback capacitor  $C_F$ , resulting in a change in voltage,  $dV$ , equal to  $dQ/C_F$ .

Figure 1. Comparison of LT1113 and LT1124 Total Output 1kHz Voltage Noise Versus Source Resistance

## APPLICATIONS INFORMATION

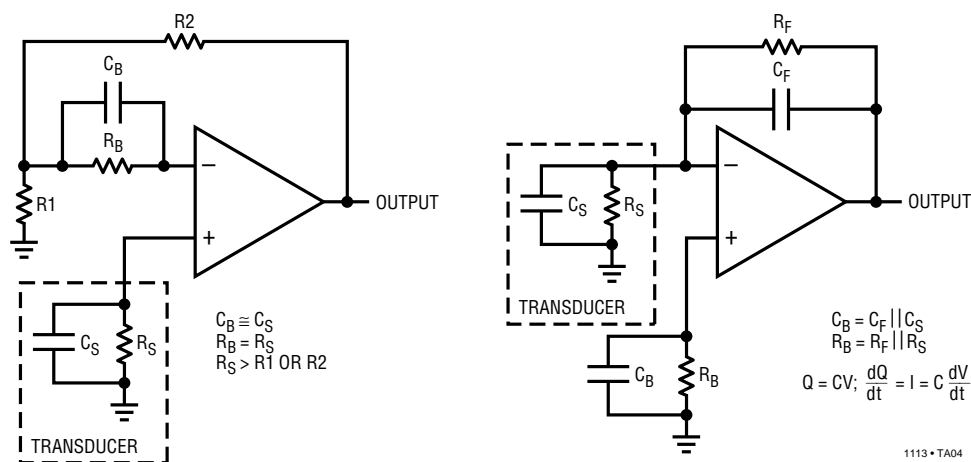

Figure 2. Noninverting and Inverting Gain Configurations

The gain therefore is  $1 + C_F/C_S$ . For unity gain, the  $C_F$  should equal the transducer capacitance plus the input capacitance of the LT1113 and  $R_F$  should equal  $R_S$ . In the noninverting mode example, the transducer current is converted to a change in voltage by the transducer capacitance; this voltage is then buffered by the LT1113 with a gain of  $1 + R_1/R_2$ . A DC path is provided by  $R_S$ , which is either the transducer impedance or an external resistor. Since  $R_S$  is usually several orders of magnitude greater than the parallel combination of  $R_1$  and  $R_2$ ,  $R_B$  is added to balance the DC offset caused by the noninverting input bias current and  $R_S$ . The input bias currents, although small at room temperature, can create significant errors over increasing temperature, especially with transducer resistances of up to  $100\text{M}\Omega$  or more. The optimum value for  $R_S$  is determined by equating the thermal noise ( $4kTR_S$ ) to the current noise times  $R_S$ ,  $(2qI_B) R_S$ , resulting in  $R_B = 2V_T/I_B$ . A parallel capacitor,  $C_B$ , is used to cancel the phase shift caused by the op amp input capacitance and  $R_B$ .

### Reduced Power Supply Operation

The LT1113 can be operated from  $\pm 5\text{V}$  supplies for lower power dissipation resulting in lower  $I_B$  and noise at the

expense of reduced dynamic range. To illustrate this benefit, let's take the following example:

An LT1113CS8 operates at an ambient temperature of  $25^\circ\text{C}$  with  $\pm 15\text{V}$  supplies, dissipating  $318\text{mW}$  of power (typical supply current =  $10.6\text{mA}$  for the dual). The S8 package has a  $\theta_{JA}$  of  $190^\circ\text{C/W}$ , which results in a die temperature increase of  $60.4^\circ\text{C}$  or a room temperature die operating temperature of  $85.4^\circ\text{C}$ . At  $\pm 5\text{V}$  supplies, the die temperature increases by only one third of the previous amount or  $20.1^\circ\text{C}$  resulting in a typical die operating temperature of only  $45.1^\circ\text{C}$ . A 40 degree reduction of die temperature is achieved at the expense of a  $20\text{V}$  reduction in dynamic range. If no DC correction resistor is used at the input, the input referred offset will be the input bias current at the operating die temperature times the transducer resistance (refer to Input Bias and Offset Currents vs Chip Temperature graph in Typical Performance Characteristics section). A  $100\text{mV}$  input  $V_{OS}$  is the result of a  $1\text{nA}$   $I_B$  (at  $85^\circ\text{C}$ ) dropped across a  $100\text{M}\Omega$  transducer resistance; at  $\pm 5\text{V}$  supplies, the input offset is only  $28\text{mV}$  ( $I_B$  at  $45^\circ\text{C}$  is  $280\text{pA}$ ). Careful selection of a DC correction resistor ( $R_B$ ) will reduce the IR errors due to  $I_B$  by an order of magnitude. A further reduction of IR errors can be

## APPLICATIONS INFORMATION

Figure 3. Voltage Follower with Input Exceeding the Common-Mode Range ( $V_S = \pm 5V$ )

achieved by using a DC servo circuit shown in the applications section of this data sheet. The DC servo has the advantage of reducing a wide range of IR errors to the millivolt level over a wide temperature variation. The preservation of dynamic range is especially important when reduced supplies are used, since input bias currents can exceed the nanoamp level for die temperatures over  $85^{\circ}\text{C}$ .

To take full advantage of a wide input common-mode range, the LT1113 was designed to eliminate phase reversal. Referring to the photographs shown in Figure 3, the LT1113 is shown operating in the follower mode ( $A_V = +1$ ) at  $\pm 5V$  supplies with the input swinging  $\pm 5.2V$ . The output of the LT1113 clips cleanly and recovers with no phase reversal, unlike the competition as shown by the last photograph. This has the benefit of preventing lock-up in servo systems and minimizing distortion components. The effect of input and output overdrive on one amplifier has no effect on the other, as each amplifier is biased independently.

### Advantages of Matched Dual Op Amps

In many applications the performance of a system depends on the matching between two operational amplifiers rather than the individual characteristics of the two op amps. Two or three op amp instrumentation amplifiers, tracking voltage references and low drift active filters are some of the circuits requiring matching between two op amps.

The well-known triple op amp configuration in Figure 4 illustrates these concepts. Output offset is a function of the difference between the two halves of the LT1113. This error cancellation principle holds for a considerable number of input referred parameters in addition to offset voltage and bias current. Input bias current will be the average of the two noninverting input currents ( $I_{B+}$ ). The difference between these two currents ( $\Delta I_{B+}$ ) is the offset current of the instrumentation amplifier. Common-mode and power supply rejections will be dependent only on the match between the two amplifiers (assuming perfect resistor matching).

## APPLICATIONS INFORMATION

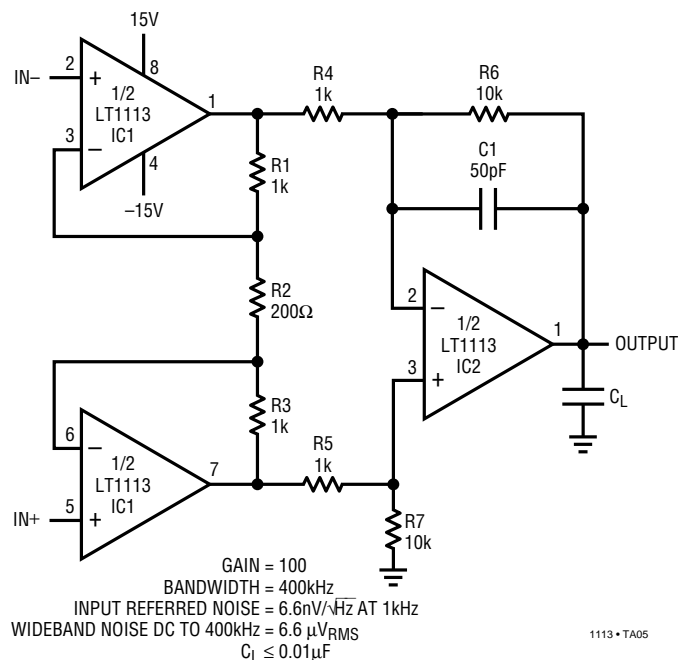

Figure 4. Three Op Amp Instrumentation Amplifier

The concepts of common-mode and power supply rejection ratio match ( $\Delta\text{CMRR}$  and  $\Delta\text{PSRR}$ ) are best demonstrated with a numerical example:

Assume  $\text{CMRR}_A = +50\mu\text{V/V}$  or 86dB,

and  $\text{CMRR}_B = +39\mu\text{V/V}$  or 88dB,

then  $\Delta\text{CMRR} = 11\mu\text{V/V}$  or 99dB;

if  $\text{CMRR}_B = -39\mu\text{V/V}$  which is still 88dB,

then  $\Delta\text{CMRR} = 89\mu\text{V/V}$  or 81dB

Clearly the LT1113, by specifying and guaranteeing all of these matching parameters, can significantly improve the performance of matching-dependent circuits.

Typical performance of the instrumentation amplifier:

Input offset voltage = 0.8mV

Input bias current = 320pA

Input offset current = 10pA

Input resistance =  $10^{11}\Omega$

Input noise =  $3.4\mu\text{V}_{\text{P-P}}$

### High Speed Operation

The low noise performance of the LT1113 was achieved by making the input JFET differential pair large to maximize the first stage gain. Increasing the JFET geometry also increases the parasitic gate capacitance, which if left unchecked, can result in increased overshoot and ringing. When the feedback around the op amp is resistive ( $R_F$ ), a pole will be created with  $R_F$ , the source resistance and capacitance ( $R_S, C_S$ ), and the amplifier input capacitance ( $C_{\text{IN}} = 27\text{pF}$ ). In closed loop gain configurations and with  $R_S$  and  $R_F$  in the kilohm range (Figure 5), this pole can create excess phase shift and even oscillation. A small capacitor ( $C_F$ ) in parallel with  $R_F$  eliminates this problem. With  $R_S(C_S + C_{\text{IN}}) = R_F C_F$ , the effect of the feedback pole is completely removed.

# TYPICAL APPLICATIONS

## Accelerometer Amplifier with DC Servo

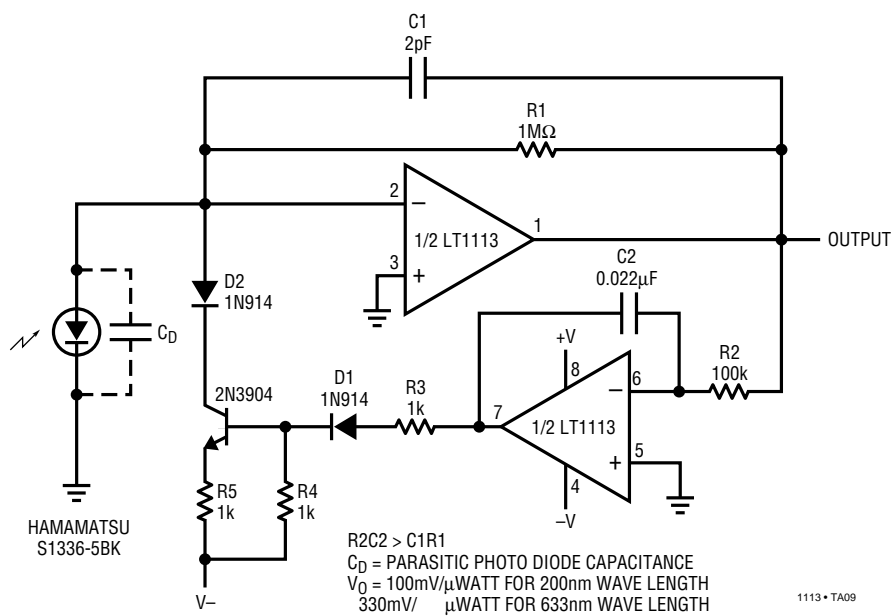

## Paralleling Amplifiers to Reduce Voltage Noise

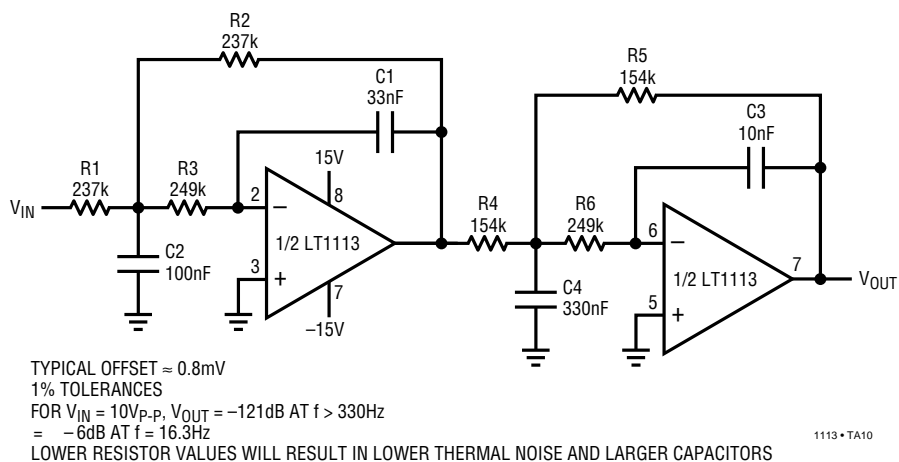

## TYPICAL APPLICATIONS

### Low Noise Light Sensor with DC Servo

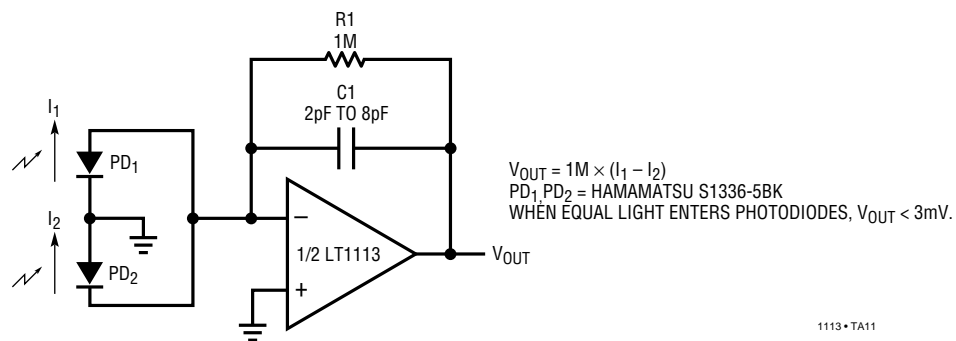

### 10Hz Fourth Order Chebyshev Lowpass Filter (0.01dB Ripple)

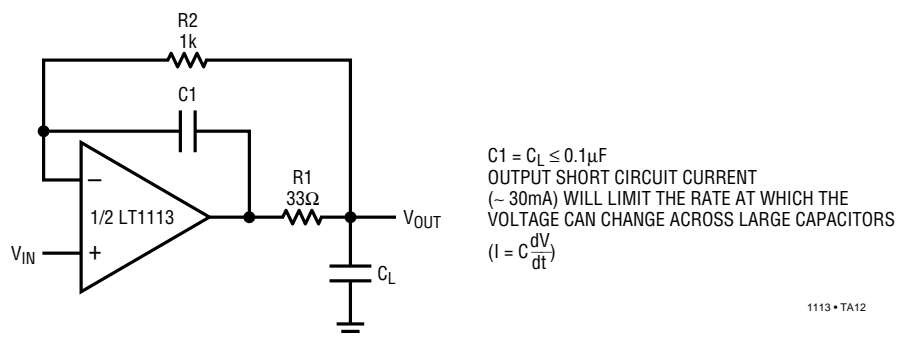

## TYPICAL APPLICATIONS

### Light Balance Detection Circuit

### Unity Gain Buffer with Extended Load Capacitance Drive Capability

LT1113

## PACKAGE DESCRIPTION

Dimensions in inches (millimeters) unless otherwise noted.

### J8 Package 8-Lead Ceramic DIP

NOTE: LEAD DIMENSIONS APPLY TO SOLDER DIP OR TIN PLATE LEADS.

#### CORNER LEADS OPTION (4 PLCS)

J8 0293

### N8 Package 8-Lead Plastic DIP

N8 0392

### S8 Package 8-Lead Plastic SOIC

S08 0392
