

QUAD DIFFERENTIAL PECL RECEIVERS

FEATURES

- Functional Replacement for the Agere BRF1A
- Pin Equivalent to General Trade 26LS32
- High Input Impedance Approximately 8 k Ω
- <2.6-ns Maximum Propagation Delay
- TB5R3 Provides 50-mV Hysteresis (Typical)
- -1.1-V to 7.1-V Common-Mode Input Voltage Range
- Single 5-V $\pm 10\%$ Supply
- ESD Protection HBM > 3 kV and CDM > 2 kV
- Operating Temperature Range: -40°C to 85°C
- Available in Gull-Wing SOIC (JEDEC MS-013, DW) and SOIC (D) Package

APPLICATIONS

- Digital Data or Clock Transmission Over Balanced Lines

DESCRIPTION

These quad differential receivers accept digital data over balanced transmission lines. They translate differential input logic levels to TTL output logic levels.

The TB5R3 is a pin- and function-compatible replacement for the Agere systems BRF1A; it includes 3-kV HBM and 2-kV CDM ESD protection.

The power-down loading characteristics of the receiver input circuit are approximately 8 k Ω relative to the power supplies; hence they do not load the transmission line when the circuit is powered down.

The packaging for this differential line receiver is a 16-pin gull wing SOIC (DW) or a 16 pin SOIC (D).

The enable inputs of this device include internal pull-up resistors of approximately 40 k Ω that are connected to V_{CC} to ensure a logical high level input if the inputs are open circuited.

TYPICAL CHARACTERISTICS

NOTE: This graph is included as an aid to the system designers. Total circuit delay varies with load capacitance. The total delay is the sum of the delay due to external capacitance and the intrinsic delay of the device. Intrinsic delay is listed in the table above as the 0 pF load condition. The incremental increase in delay between the 0 pF load condition and the actual total load capacitance represents the extrinsic, or external delay contributed by the load.

APPLICATION INFORMATION

Power Dissipation

The power dissipation rating, often listed as the package dissipation rating, is a function of the ambient temperature, T_A , and the airflow around the device. This rating correlates with the device's maximum junction temperature, sometimes listed in the absolute maximum ratings tables. The maximum junction temperature accounts for the processes and materials used to fabricate and package the device, in addition to the desired life expectancy.

There are two common approaches to estimating the internal die junction temperature, T_J . In both of these methods, the device internal power dissipation P_D needs to be calculated. This is done by totaling the supply power(s) to arrive at the system power dissipation:

$$\sum (V_{Sn} \times I_{Sn}) \quad (1)$$

and then subtracting the total power dissipation of the external load(s):

$$\sum (V_{Ln} \times I_{Ln}) \quad (2)$$

The first T_J calculation uses the power dissipation and ambient temperature, along with one parameter: θ_{JA} , the junction-to-ambient thermal resistance, in degrees Celsius per watt.

The product of P_D and θ_{JA} is the junction temperature rise above the ambient temperature. Therefore:

$$T_J = T_A + (P_D \times \theta_{JA}) \quad (3)$$

Figure 10. Thermal Impedance vs Air Flow

Note that θ_{JA} is highly dependent on the PCB on

which the device is mounted and on the airflow over the device and PCB. JEDEC/EIA has defined standardized test conditions for measuring θ_{JA} . Two commonly used conditions are the low-K and the high-K boards, covered by EIA/JESD51-3 and EIA/JESD51-7 respectively. Figure 10 shows the low-K and high-K values of θ_{JA} versus air flow for this device and its package options.

The standardized θ_{JA} values may not accurately represent the conditions under which the device is used. This can be due to adjacent devices acting as heat sources or heat sinks, to nonuniform airflow, or to the system PCB having significantly different thermal characteristics than the standardized test PCBs. The second method of system thermal analysis is more accurate. This calculation uses the power dissipation and ambient temperature, along with two device and two system-level parameters:

- θ_{JC} , the junction-to-case thermal resistance, in degrees Celsius per watt
- θ_{JB} , the junction-to-board thermal resistance, in degrees Celsius per watt
- θ_{CA} , the case-to-ambient thermal resistance, in degrees Celsius per watt
- θ_{BA} , the board-to-ambient thermal resistance, in degrees Celsius per watt.

In this analysis, there are two parallel paths, one through the case (package) to the ambient, and another through the device to the PCB to the ambient. The system-level junction-to-ambient thermal impedance, $\theta_{JA(S)}$, is the equivalent parallel impedance of the two parallel paths:

$$T_J = T_A + (P_D \times \theta_{JA(S)}) \quad (4)$$

where

$$\theta_{JA(S)} = \frac{[(\theta_{JC} + \theta_{CA}) \times (\theta_{JB} + \theta_{BA})]}{(\theta_{JC} + \theta_{CA} + \theta_{JB} + \theta_{BA})} \quad (5)$$

The device parameters θ_{JC} and θ_{JB} account for the internal structure of the device. The system-level parameters θ_{CA} and θ_{BA} take into account details of the PCB construction, adjacent electrical and mechanical components, and the environmental conditions including airflow. Finite element (FE), finite difference (FD), or computational fluid dynamics (CFD) programs can determine θ_{CA} and θ_{BA} . Details on using these programs are beyond the scope of this data sheet, but are available from the software manufacturers.
