# 16－Bit， 570 kSPS PulSAR ${ }^{\text {® }}$ Unipolar CMOS ADC 

## ANALOG DEVICES

 AD7664＊
## FEATURES

Throughput：

## 570 kSPS（Warp Mode）

500 kSPS（Normal Mode）
444 kSPS（Impulse Mode）
INL：$\pm 2.5$ LSB Max（ $\pm 0.0038 \%$ of Full Scale）
16－Bit Resolution with No Missing Codes
S／（N＋D）： 90 dB Typ＠ 45 kHz
THD：－100 dB Typ＠ 45 kHz
Analog Input Voltage Range： 0 V to 2.5 V
Both AC and DC Specifications
No Pipeline Delay
Parallel and Serial 5 V／3 V Interface
SPI ${ }^{\circledR} /$ OSPI ${ }^{\text {TM }} / \mathrm{MICROWIRE}{ }^{\text {TM }} /$ DSP Compatible
Single 5 V Supply Operation
Power Dissipation 115 mW Maximum， $21 \mu \mathrm{~W}$＠ 100 SPS
Power－Down Mode： $7 \mu$ W Max
Package：48－Lead Quad Flat Pack（LOFP） 48－Lead Chip Scale Package（LFCSP）
Pin－to－Pin Compatible Upgrade of the AD7660

## APPLICATIONS

Data Acquisition
Instrumentation
Digital Signal Processing
Spectrum Analysis
Medical Instruments
Battery－Powered Systems
Process Control

## GENERAL DESCRIPTION

The AD7664 is a 16 －bit， 570 kSPS ，charge redistribution SAR， analog－to－digital converter that operates from a single 5 V power supply．The part contains a high speed 16 －bit sampling ADC， an internal conversion clock，error correction circuits，and both serial and parallel system interface ports．
The AD7664 is hardware factory－calibrated and is comprehensively tested to ensure such ac parameters as signal－to－noise ratio（SNR） and total harmonic distortion（THD），in addition to the more traditional dc parameters of gain，offset，and linearity．
It features a very high sampling rate mode（Warp），a fast mode （Normal）for asynchronous conversion rate applications，and for low power applications，a reduced power mode（Impulse）where the power is scaled with the throughput．

## NOTES

${ }^{1}$ LSB means least significant bit. With the 0 V to 2.5 V input range, one LSB is $38.15 \mu \mathrm{~V}$.
${ }^{2}$ See Definition of Specifications section. These specifications do not include the error contribution from the external reference.
${ }^{3}$ All specifications in dB are referred to a full-scale input FS. Tested with an input signal at 0.5 dB below full-scale unless otherwise specified.
${ }^{4}$ In Normal Mode.
${ }^{5}$ Tested in Parallel Reading Mode.
${ }^{6}$ In Impulse Mode.
${ }^{7}$ With all digital inputs forced to OVDD or OGND, respectively.
${ }^{8}$ Contact factory for extended temperature range.
Specifications subject to change without notice.

## TIMING SPECIFICATIONS ( $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}, \operatorname{AVDD}=\operatorname{DVDD}=5 \mathrm{~V}$, OVDD $=2.7 \mathrm{~V}$ to 5.25 V , unless otherwise noted.)

## NOTES

${ }^{1}$ In Warp Mode only, the maximum time between conversions is 1 ms ; otherwise, there is no required maximum time.
${ }^{2}$ In Serial Interface Modes, the SYNC, SCLK, and SDOUT timings are defined with a maximum load $\mathrm{C}_{\mathrm{L}}$ of 10 pF ; otherwise, the load is 60 pF maximum.
${ }^{3}$ If the polarity of SCLK is inverted, the timing references of SCLK are also inverted.

## AD7664

## ABSOLUTE MAXIMUM RATINGS ${ }^{1}$

${ }^{1}$ Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
${ }^{2}$ See Analog Input section.
pecification is for the device in free air
Specification is for device in free air:
48 -Lead LFCSP; $\theta_{\mathrm{JA}}=26^{\circ} \mathrm{C} / \mathrm{W}$.

* IN SERIAL INTERFACE MODES, THE SYNC, SCLK, AND SDOUT TIMINGS ARE DEFINED WITH A MAXIMUM LOAD $\mathrm{C}_{\mathrm{L}}$ OF 10 pF ; OTHERWISE, THE LOAD IS 60pF MAXIMUM.

NOTES
${ }^{1}$ This board can be used as a standalone evaluation board or in conjunction with the EVAL-CONTROL-BRD2 for evaluation/ demonstration purposes.
${ }^{2}$ This board allows a PC to control and communicate with all Analog Devices evaluation boards ending in the CB designators.

## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD7664 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION

## PIN FUNCTION DESCRIPTIONS

| Pin No. | Mnemonic | Type | Description |
| :---: | :---: | :---: | :---: |
| 1 | AGND | P | Analog Power Ground Pin. |
| 2 | AVDD | P | Input Analog Power Pins. Nominally 5 V . |
| $\begin{aligned} & 3,40-42, \\ & 44-48 \end{aligned}$ | NC |  | No Connect. |
| 4 | DGND | DI | Must Be Tied to the Ground Where DVDD Is Referred. |
| 5 | OB/2C | DI | Straight Binary/Binary Twos Complement. When OB/2C is HIGH, the digital output is straight binary; when LOW, the MSB is inverted resulting in a twos complement output from its internal shift register. |
| 6 | WARP | DI | Mode Selection. When HIGH and IMPULSE LOW, this input selects the fastest mode, the maximum throughput is achievable, and a minimum conversion rate must be applied in order to guarantee full specified accuracy. When LOW, full accuracy is maintained independent of the minimum conversion rate. |
| 7 | IMPULSE | DI | Mode Selection. When HIGH and WARP LOW, this input selects a reduced power mode. In this mode, the power dissipation is approximately proportional to the sampling rate. |
| 8 | SER $\overline{\text { PAR }}$ | DI | Serial/Parallel Selection Input. When LOW, the Parallel Port is selected; when HIGH, the Serial Interface Mode is selected and some bits of the DATA bus are used as a Serial Port. |
| 9-12 | D [0:3] | DO | Bit 0 to Bit 3 of the Parallel Port Data Output Bus. These pins are always outputs, regardless of the state of SER $\overline{\text { PAR }}$. |
| 13 | $\begin{aligned} & \mathrm{D} 4 \\ & \text { or EXT/INT } \end{aligned}$ | DI/O | When SER $\overline{\mathrm{PAR}}$ is LOW, this output is used as Bit 4 of the Parallel Port Data Output Bus. When SER $\overline{\mathrm{PAR}}$ is HIGH, this input, part of the Serial Port, is used as a digital select input for choosing the internal or an external data clock. With EXT/俭T tied LOW, the internal clock is selected on the SCLK output. With EXT//INT set to a logic HIGH, output data is synchronized to an external clock signal connected to the SCLK input. |
| 14 | $\begin{aligned} & \text { D5 } \\ & \text { or INVSYNC } \end{aligned}$ | DI/O | When SER $\overline{\mathrm{PAR}}$ is LOW, this output is used as Bit 5 of the Parallel Port Data Output Bus. When SER $\overline{\text { PAR }}$ is HIGH, this input, part of the Serial Port, is used to select the active state of the SYNC signal. It is active in both Master and Slave Mode. When LOW, SYNC is active HIGH. When HIGH, SYNC is active LOW. |
| 15 | D6 <br> or INVSCLK | DI/O | When SER $\overline{\mathrm{PAR}}$ is LOW, this output is used as Bit 6 of the Parallel Port Data Output Bus. When SER $/ \overline{\mathrm{PAR}}$ is HIGH, this input, part of the Serial Port, is used to invert the SCLK signal. It is active in both Master and Slave Mode. |

| Pin No. | Mnemonic | Type | Description |
| :---: | :---: | :---: | :---: |
| 16 | $\begin{aligned} & \text { D7 } \\ & \text { or RDC/SDIN } \end{aligned}$ | DI/O | When SER $\overline{\mathrm{PAR}}$ is LOW, this output is used as Bit 7 of the Parallel Port Data Output Bus. <br> When SER $\overline{P A R}$ is HIGH, this input, part of the Serial Port, is used as either an external data input or a Read Mode selection input depending on the state of EXT $\overline{\mathrm{INT}}$. <br> When EXT/ $\overline{\mathrm{INT}}$ is HIGH, RDC/SDIN could be used as a data input to daisy-chain the conversion results from two or more ADCs onto a single SDOUT line. The digital data level on SDIN is output on DATA with a delay of 16 SCLK periods after the initiation of the read sequence. <br> When EXT/ $\overline{\mathrm{INT}}$ is LOW, RDC/SDIN is used to select the Read Mode. When RDC/SDIN is HIGH, the data is output on SDOUT during conversion. When RDC/SDIN is LOW, the data can be output on SDOUT only when the conversion is complete. |
| 17 | OGND | P | Input/Output Interface Digital Power Ground. |
| 18 | OVDD | P | Input/Output Interface Digital Power. Nominally at the same supply as the supply of the host interface ( 5 V or 3 V ). |
| 19 | DVDD | P | Digital Power. Nominally at 5 V . |
| 20 | DGND | P | Digital Power Ground. |
| 21 | $\begin{aligned} & \text { D8 } \\ & \text { or SDOUT } \end{aligned}$ | DO | When SER $\overline{\operatorname{PAR}}$ is LOW, this output is used as Bit 8 of the Parallel Port Data Output Bus. When SER $\sqrt{\text { PAR }}$ is HIGH, this output, part of the Serial Port, is used as a serial data output synchronized to SCLK. Conversion results are stored in an on-chip register. The AD7664 provides the conversion result, MSB first, from its internal shift register. The DATA format is determined by the logic level of OB/2C. In Serial Mode, when EXT $\overline{\mathrm{INT}}$ is LOW, SDOUT is valid on both edges of SCLK. <br> In Serial Mode, when EXT/ $\overline{\mathrm{INT}}$ is HIGH: <br> If INVSCLK is LOW, SDOUT is updated on the SCLK rising edge and valid on the next falling edge. <br> If INVSCLK is HIGH, SDOUT is updated on the SCLK falling edge and valid on the next rising edge. |
| 22 | $\begin{aligned} & \text { D9 } \\ & \text { or SCLK } \end{aligned}$ | DI/O | When SER $/ \overline{\mathrm{PAR}}$ is LOW, this output is used as Bit 9 of the Parallel Port Data Output Bus. <br> When SER $\overline{\mathrm{PAR}}$ is HIGH, this pin, part of the Serial Port, is used as a serial data clock input or output, dependent upon the logic state of the EXT/INT pin. The active edge where the data SDOUT is updated depends upon the logic state of the INVSCLK pin. |
| 23 | D10 <br> or SYNC | DO | When SER $\overline{\text { PAR }}$ is LOW, this output is used as the Bit 10 of the Parallel Port Data Output Bus. When SER $/ \overline{\mathrm{PAR}}$ is HIGH, this output, part of the Serial Port, is used as a digital output frame synchronization for use with the internal data clock (EXT/INT = Logic LOW). When a read sequence is initiated and INVSYNC is LOW, SYNC is driven HIGH and remains HIGH while the SDOUT output is valid. When a read sequence is initiated and INVSYNC is HIGH, SYNC is driven LOW and remains LOW while the SDOUT output is valid. |
| 24 | D11 <br> or RDERROR | DO | When SER $\overline{\mathrm{PAR}}$ is LOW, this output is used as Bit 11 of the Parallel Port Data Output Bus. When SER $/ \overline{\mathrm{PAR}}$ is HIGH and EXT $/ \overline{\mathrm{INT}}$ is HIGH, this output, part of the Serial Port, is used as an incomplete read error flag. In Slave Mode, when a data read is started and not complete when the following conversion is complete, the current data is lost and RDERROR is pulsed HIGH. |
| 25-28 | D [12:15] | DO | Bit 12 to Bit 15 of the Parallel Port Data Output Bus. These pins are always outputs regardless of the state of SER $\overline{\mathrm{PAR}}$. |
| 29 | BUSY | DO | Busy Output. Transitions HIGH when a conversion is started and remains HIGH until the conversion is complete and the data is latched into the on-chip shift register. The falling edge of BUSY could be used as a data-ready clock signal. |
| 30 | DGND | P | Must Be Tied to Digital Ground. |
| 31 | $\overline{\mathrm{RD}}$ | DI | Read Data. When $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ are both LOW, the interface parallel or serial output bus is enabled. |
| 32 | $\overline{\mathrm{CS}}$ | DI | Chip Select. When $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ are both LOW, the interface parallel or serial output bus is enabled. $\overline{\mathrm{CS}}$ is also used to gate the external clock. |
| 33 | RESET | DI | Reset Input. When set to a logic HIGH, reset the AD7664. Current conversion if any is aborted. If not used, this pin could be tied to DGND. |
| 34 | PD | DI | Power-Down Input. When set to a logic HIGH, power consumption is reduced and conversions are inhibited after the current one is completed. |

## DEFINITION OF SPECIFICATIONS

## Integral Nonlinearity Error (INL)

Linearity error refers to the deviation of each individual code from a line drawn from negative full scale through positive full scale. The point used as negative full scale occurs 1/2 LSB before the first code transition. Positive full scale is defined as a level $11 / 2$ LSB beyond the last code transition. The deviation is measured from the middle of each code to the true straight line.

## Differential Nonlinearity Error (DNL)

In an ideal ADC, code transitions are 1 LSB apart. Differential nonlinearity is the maximum deviation from this ideal value. It is often specified in terms of resolution for which no missing codes are guaranteed.

## Full-Scale Error

The last transition (from $011 \ldots 10$ to $011 \ldots 11$ in twos complement coding) should occur for an analog voltage $11 / 2$ LSB below the nominal full scale ( 2.49994278 V for the $0 \mathrm{~V}-2.5 \mathrm{~V}$ range). The full-scale error is the deviation of the actual level of the last transition from the ideal level.

## Unipolar Zero Error

The first transition should occur at a level $1 / 2$ LSB above analog ground ( $19.073 \mu \mathrm{~V}$ for the $0 \mathrm{~V}-2.5 \mathrm{~V}$ range). Unipolar zero error is the deviation of the actual transition from that point.

## Spurious-Free Dynamic Range (SFDR)

The difference, in decibels (dB), between the rms amplitude of the input signal and the peak spurious signal.

## Effective Number of Bits (ENOB)

ENOB is a measurement of the resolution with a sine wave input. It is related to $\mathrm{S} /(\mathrm{N}+\mathrm{D})$ by the following formula:

$$
E N O B=\left(S /[N+D]_{d B}-1.76\right) / 6.02
$$

and is expressed in bits.

## Total Harmonic Distortion (THD)

THD is the ratio of the rms sum of the first five harmonic components to the rms value of a full-scale input signal and is expressed in decibels.

Signal-to-Noise Ratio (SNR)
SNR is the ratio of the rms value of the actual input signal to the rms sum of all other spectral components below the Nyquist frequency, excluding harmonics and dc. The value for SNR is expressed in decibels.

## Signal to (Noise + Distortion) Ratio (S/[N+D])

$\mathrm{S} /(\mathrm{N}+\mathrm{D})$ is the ratio of the rms value of the actual input signal to the rms sum of all other spectral components below the Nyquist frequency, including harmonics but excluding dc. The value for $\mathrm{S} /(\mathrm{N}+\mathrm{D})$ is expressed in decibels.

## Aperture Delay

Aperture delay is a measure of the acquisition performance and is measured from the falling edge of the CNVST input to when the input signal is held for a conversion.

## Transient Response

The time required for the AD7664 to achieve its rated accuracy after a full-scale step function is applied to its input.

## Overvoltage Recovery

The time required for the ADC to recover to full accuracy after an analog input signal $150 \%$ of full-scale is reduced to $50 \%$ of the full-scale value.

## AD7664-Typical Performance Characteristics

TPC 1. Integral Nonlinearity vs. Code

TPC 2. Histogram of 16,384 Conversions of a DC Input at the Code Transition

TPC 3. Typical Positive INL Distribution (600 Units)

TPC 14. Typical Delay vs. Load Capacitance $C_{L}$

## AD7664

## CIRCUIT INFORMATION

The AD7664 is a very fast, low power, single-supply, precise 16-bit analog-to-digital converter (ADC). The AD7664 features different modes to optimize performances according to the applications.
In Warp Mode, the AD7664 is capable of converting 570,000 samples per second ( 570 kSPS ).
The AD7664 provides the user with an on-chip track-and-hold, successive-approximation ADC that does not exhibit any pipeline or latency, making it ideal for multiple multiplexed channel applications.
The AD7664 can be operated from a single 5 V supply and interfaced to either 5 V or 3 V digital logic. It is housed in a 48-lead LQFP package or a 48-lead LFCSP package that saves space and allows flexible configurations as either a serial or parallel interface. The AD7664 is a pin-to-pin compatible upgrade of the AD7660.

## CONVERTER OPERATION

The AD7664 is a successive-approximation analog-to-digital converter based on a charge redistribution DAC. Figure 3 shows the simplified schematic of the ADC. The capacitive DAC consists of an array of 16 binary weighted capacitors and an additional LSB capacitor. The comparator's negative input is connected to a dummy capacitor of the same value as the capacitive DAC array.
During the acquisition phase, the common terminal of the array tied to the comparator's positive input is connected to AGND via $\mathrm{SW}_{\mathrm{A}}$. All independent switches are connected to the analog
input IN. Thus, the capacitor array is used as a sampling capacitor and acquires the analog signal on the IN input. Similarly, the dummy capacitor acquires the analog signal on the INGND input.
When the CNVST input goes LOW, a conversion phase is initiated. When the conversion phase begins, $\mathrm{SW}_{\mathrm{A}}$ and $\mathrm{SW}_{\mathrm{B}}$ are opened first. The capacitor array and the dummy capacitor are then disconnected from the inputs and connected to the REFGND input. Therefore, the differential voltage between $\mathbb{N}$ and INGND captured at the end of the acquisition phase is applied to the comparator inputs, causing the comparator to become unbalanced. By switching each element of the capacitor array between REFGND or REF, the comparator input varies by binary-weighted voltage steps ( $\mathrm{V}_{\mathrm{REF}} / 2, \mathrm{~V}_{\mathrm{REF}} / 4, \ldots \mathrm{~V}_{\mathrm{REF}} / 65536$ ). The control logic toggles these switches, starting with the MSB first, to bring the comparator back into a balanced condition. After the completion of this process, the control logic generates the ADC output code and brings BUSY output LOW.

## Modes of Operation

The AD7664 features three modes of operation: Warp, Normal, and Impulse. Each of these modes is suitable for specific applications.

The Warp Mode allows the fastest conversion rate up to 570 kSPS . However, in this mode and this mode only, the full specified accuracy is guaranteed only when the time between conversions does not exceed 1 ms . If the time between two consecutive conversions is longer than 1 ms , for instance, after power-up, the first conversion result should be ignored. This mode makes the AD7664 ideal for applications where both high accuracy and fast sample rate are required.

Figure 3. ADC Simplified Schematic

## AD7664

The Normal Mode is the fastest mode ( 500 kSPS ) without any limitation on the time between conversions. This mode makes the AD7664 ideal for asynchronous applications such as data acquisition systems, where both high accuracy and fast sample rate are required.
The Impulse Mode, the lowest power dissipation mode, allows power saving between conversions. When operating at 100 SPS, for example, it typically consumes only $21 \mu \mathrm{~W}$. This feature makes the AD7664 ideal for battery-powered applications.

## Transfer Functions

Using the $\mathrm{OB} / \overline{2 \mathrm{C}}$ digital input, the AD7664 offers two output codings: straight binary and twos complement. The LSB size is $\mathrm{V}_{\mathrm{REF}} / 65536$, which is about $38.15 \mu \mathrm{~V}$. The ideal transfer characteristics for the AD7664 are shown in Figure 4 and Table II.

Table II. Output Codes and Ideal Input Voltages

|  |  | Digital Output Code <br> Hexa |  |
| :--- | :--- | :--- | :--- |
| Description | Analog <br> Input | Straight <br> Binary | Twos <br> Complement |
| FSR - 1 LSB | 2.499962 V | FFFF $^{1}$ | $7 \mathrm{FFF}^{1}$ |
| FSR - 2 LSB | 2.499923 V | FFFE | 7 FFE |
| Midscale + 1 LSB | 1.250038 V | 8001 | 0001 |
| Midscale | 1.25 V | 8000 | 0000 |
| Midscale - 1 LSB | 1.249962 V | 7 FFF | FFFF |
| -FSR + 1 LSB | $38 \mu \mathrm{~V}$ | 0001 | 8001 |
| -FSR | 0 V | $0000^{2}$ | $8000^{2}$ |

NOTES
${ }^{1}$ This is also the code for overrange analog input $\left(\mathrm{V}_{\text {IN }}-\mathrm{V}_{\text {INGND }}\right.$ above
$\mathrm{V}_{\text {Ref }}-\mathrm{V}_{\text {Refgnd }}$ ).
${ }^{2}$ This is also the code for underrange analog input ( $\mathrm{V}_{\text {IN }}$ below $\mathrm{V}_{\text {INGND }}$ ).

${ }^{2}$ THE AD8021 IS RECOMMENDED WITH A COMPENSATION CAPACITOR $C_{C}=10 \mathrm{pF}$, TYPE CERAMIC NPO. ${ }^{3}$ OPTIONAL LOW JITTER CNVST.

## AD7664

## Analog Input

Figure 6 shows an equivalent circuit of the input structure of the AD7664.

Figure 6. Equivalent Analog Input Circuit
The two diodes D1 and D2 provide ESD protection for the analog inputs IN and INGND. Care must be taken to ensure that the analog input signal never exceeds the supply rails by more than 0.3 V . This will cause these diodes to become forwardbiased and start conducting current. These diodes can handle a forward-biased current of 100 mA maximum. For instance, these conditions could eventually occur when the input buffer's (U1) supplies are different from AVDD. In such cases, an input buffer with a short circuit current limitation can be used to protect the part.
This analog input structure allows the sampling of the differential signal between IN and INGND. Unlike other converters, the INGND input is sampled at the same time as the IN input. By using this differential input, small signals common to both inputs are rejected, as shown in Figure 7, which represents the typical CMRR over frequency. For instance, by using INGND to sense a remote signal ground, difference of ground potentials between the sensor and the local ADC ground are eliminated.

Figure 7. Analog Input CMRR vs. Frequency
During the acquisition phase, the impedance of the analog input IN can be modeled as a parallel combination of capacitor C1 and the network formed by the series connection of R1 and C2. Capacitor C1 is primarily the pin capacitance. The resistor R1 is typically $140 \Omega$ and is a lumped component made up of some serial resistors and the on resistance of the switches. The capacitor C 2 is typically 60 pF and is mainly the ADC sampling capacitor. During the conversion phase, where the switches are opened, the input impedance is limited to C 1 . The R1, C2 makes a one-pole low-pass filter that reduces the undesirable aliasing effect and limits the noise.
When the source impedance of the driving circuit is low, the AD7664 can be driven directly. Large source impedances will
significantly affect the ac performances, especially the total harmonic distortion (THD). The maximum source impedance depends on the amount of THD that can be tolerated. The THD degrades in function of the source impedance and the maximum input frequency as shown in Figure 8.

Figure 8. THD vs. Analog Input Frequency and Source Resistance

## Driver Amplifier Choice

Although the AD7664 is easy to drive, the driver amplifier needs to meet at least the following requirements:

- The driver amplifier and the AD7664 analog input circuit must be able, together, to settle for a full-scale step of the capacitor array at a 16 -bit level $(0.0015 \%)$. In the amplifier's data sheet, the settling at $0.1 \%$ to $0.01 \%$ is more commonly specified. It could significantly differ from the settling time at 16-bit level and it should, therefore, be verified prior to the driver selection. The tiny op amp AD8021, which combines ultralow noise and a high gain bandwidth, meets this settling time requirement even when used with high gain up to 13 .
- The noise generated by the driver amplifier needs to be kept as low as possible in order to preserve the SNR and transition noise performance of the AD7664. The noise coming from the driver is filtered by the AD7664 analog input circuit onepole low-pass filter made by R1 and C2 or the external filter, if any is used. The SNR degradation due to the amplifier is:

$$
S N R_{\text {LOSS }}=20 \log \left[\frac{28}{\sqrt{784+\frac{\pi}{2} f_{-3 d B}\left(N e_{N}\right)^{2}}}\right]
$$

where:
$f_{-3} d B$ is the -3 dB input bandwidth in MHz of the AD 7664 ( 18 MHz ) or the cutoff frequency of the input filter, if any used.
$N$ is the noise gain of the amplifier (1, if in buffer configuration).
$e_{N} \quad$ is the equivalent input noise voltage of the op amp in $\mathrm{nV} / \sqrt{\mathrm{Hz}}$.

## AD7664

For instance, in a driver like the AD 8021 , with an equivalent input noise of $2 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ and configured as a buffer, thus with a noise gain of 1 , the SNR degrades by 0.58 dB .

- The driver needs to have a THD performance suitable to that of the AD7664. TPC 12 gives the THD versus frequency that the driver should preferably exceed.
The AD8021 meets these requirements and is usually appropriate for almost all applications. The AD8021 needs an external compensation capacitor of 10 pF . This capacitor should have good linearity as an NPO ceramic or mica type.
The AD8022 could also be used where a dual version is needed and a gain of 1 is used.
The AD829 is another alternative where high frequency (above 100 kHz ) performance is not required. In a gain of 1 , it requires an 82 pF compensation capacitor.
The AD8610 is another option where low bias current is needed in low frequency applications.

## Voltage Reference Input

The AD7664 uses an external 2.5 V voltage reference.
The voltage reference input REF of the AD 7664 has a dynamic input impedance; it should, therefore, be driven by a low impedance source with an efficient decoupling between REF and REFGND inputs. This decoupling depends on the choice of the voltage reference, but usually consists of a $1 \mu \mathrm{~F}$ ceramic capacitor and a low ESR tantalum capacitor connected to the REF and REFGND inputs with minimum parasitic inductance. $47 \mu \mathrm{~F}$ is an appropriate value for the tantalum capacitor when used with one of the recommended reference voltages:

- The low noise, low temperature drift ADR421 and AD780 voltage references
- The low power ADR291 voltage reference
- The low cost AD1582 voltage reference

For applications using multiple AD7664s, it is more effective to buffer the reference voltage with a low noise, very stable op amp like the AD8031.
Care should also be taken with the reference temperature coefficient of the voltage reference that directly affects the full-scale accuracy, if this parameter matters. For instance, $\mathrm{a} \pm 15 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$ tempco of the reference changes the full scale by $\pm 1 \mathrm{LSB} /{ }^{\circ} \mathrm{C}$.
$\mathrm{V}_{\text {REF }}$, as mentioned in the specification table, could be increased to AVDD - 1.85 V . The benefit here is the increased SNR obtained as a result of this increase. Since the input range is defined in terms of $\mathrm{V}_{\text {REF }}$, this would essentially increase the range to make it a 0 V to 3 V input range with an AVDD above 4.85 V . The theoretical improvement as a result of this increase in reference is $1.58 \mathrm{~dB}(20 \log [3 / 2.5])$. Due to the theoretical quantization noise, however, the observed improvement is approximately 1 dB . The AD780 can be selected with a 3 V reference voltage.

## Power Supply

The AD7664 uses three sets of power supply pins: an analog 5 V supply AVDD, a digital 5 V core supply DVDD, and a digital input/output interface supply OVDD. The OVDD supply allows direct interface with any logic working between 2.7 V and 5.25 V . To reduce the number of supplies needed, the digital core
(DVDD) can be supplied through a simple RC filter from the analog supply as shown in Figure 5. The AD7664 is independent of power supply sequencing and thus free from supply voltage induced latch-up. Additionally, it is very insensitive to power supply variations over a wide frequency range, as shown in Figure 9.

## POWER DISSIPATION VERSUS THROUGHPUT

Operating currents are very low during the acquisition phase, which allows significant power savings when the conversion rate is reduced, as shown in Figure 10. This power saving depends on the mode used. In Impulse Mode, the AD7664 automatically reduces its power consumption at the end of each conversion phase. This feature makes the AD7664 ideal for very low power batteryoperated applications. It should be noted that the digital interface remains active even during the acquisition phase. To reduce the operating digital supply currents even further, the digital inputs need to be driven close to the power supply rails (i.e., DVDD or DGND for all inputs except EXT//INT, INVSYNC, INVSCLK, RDC/SDIN, and OVDD or OGND for these last four inputs).

Figure 9. PSRR vs. Frequency

Figure 10. Power Dissipation vs. Sample Rate

## AD7664

## CONVERSION CONTROL

Figure 11 shows the detailed timing diagrams of the conversion process. The AD7664 is controlled by the signal $\overline{\text { CNVST }}$, which initiates conversion. Once initiated, it cannot be restarted or aborted, even by the power-down input PD, until the conversion is complete. The CNVST signal operates independently of $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ signals.

Figure 11. Basic Conversion Timing
In Impulse Mode, conversions can be automatically initiated. If CNVST is held LOW when BUSY is LOW, the AD7664 controls the acquisition phase and then automatically initiates a new conversion. By keeping CNVST LOW, the AD7664 keeps the conversion process running by itself. It should be noted that the analog input has to be settled when BUSY goes LOW. Also, at power-up, $\overline{\text { CNVST }}$ should be brought LOW once to initiate the conversion process. In this mode, the AD7664 could sometimes run slightly faster then the guaranteed limits in the Impulse Mode of 444 kSPS . This feature does not exist in Warp or Normal Modes.

Figure 12. RESET Timing
Although $\overline{\text { CNVST }}$ is a digital signal, it should be designed with special care with fast, clean edges, and levels with minimum overshoot and undershoot or ringing.
It is a good thing to shield the $\overline{\text { CNVST }}$ trace with ground and also to add a low value serial resistor (i.e., $50 \Omega$ ) termination close to the output of the component that drives this line.
For applications where the SNR is critical, the $\overline{\text { CNVST }}$ signal should have a very low jitter. This may be achieved by using a dedicated oscillator for CNVST generation or, at least, to clock it with a high frequency, low jitter clock as shown in Figure 5.

## DIGITAL INTERFACE

The AD7664 has a versatile digital interface; it can be interfaced with the host system by using either a serial or parallel interface. The serial interface is multiplexed on the parallel databus. The AD7664 digital interface also accommodates both 3 V or 5 V logic by simply connecting the OVDD supply pin of the AD7664 to the host system interface digital supply. Finally, by using the $\mathrm{OB} / \overline{2 \mathrm{C}}$ input pin, either twos complement or straight binary coding can be used.
The two signals $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ control the interface. $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ have a similar effect, because they are OR'd together internally. When at least one of these signals is HIGH, the interface outputs are in high impedance. Usually, $\overline{\mathrm{CS}}$ allows the selection of each AD7664 in multicircuit applications and is held LOW in a single AD 7664 design. $\overline{\mathrm{RD}}$ is generally used to enable the conversion result on the databus.

Figure 13. Master Parallel Data Timing for Reading (Continuous Read)

## PARALLEL INTERFACE

The AD7664 is configured to use the parallel interface when the SER/ $\overline{\mathrm{PAR}}$ is held LOW. The data can be read either after each conversion, which is during the next acquisition phase, or during the following conversion as shown, respectively, in Figures 14 and 15 . When the data is read during the conversion, however, it is recommended that it be read-only during the first half of the conversion phase. This avoids any potential feedthrough between voltage transients on the digital interface and the most critical analog conversion circuitry.

Figure 14. Slave Parallel Data Timing for Reading (Read after Convert)

Figure 15. Slave Parallel Data Timing for Reading (Read during Convert)

## SERIAL INTERFACE

The AD7664 is configured to use the serial interface when the SER $\overline{\mathrm{PAR}}$ is held HIGH. The AD7664 outputs 16 bits of data, MSB first, on the SDOUT pin. This data is synchronized with the 16 clock pulses provided on the SCLK pin. The output data is valid on both the rising and falling edge of the data clock.

## MASTER SERIAL INTERFACE

Internal Clock
The AD7664 is configured to generate and provide the serial data clock SCLK when the EXT/INT pin is held LOW. The AD7664 also generates a SYNC signal to indicate to the host when the serial data is valid. The serial clock SCLK and the SYNC signal can be inverted, if desired. Depending on RDC/SDIN input, the data can be read after each conversion or during the following conversion. Figures 16 and 17 show the detailed timing diagrams of these two modes.

Figure 16. Master Serial Data Timing for Reading (Read after Convert)

Figure 18. Slave Serial Data Timing for Reading (Read after Convert)

Because the AD7664 is used with a fast throughput, the Master Read During Conversion Mode is the most often recommended Serial Mode, when it can be used. In this mode, the serial clock and data toggle at appropriate instants that minimize potential feedthrough between digital activity and the critical conversion decisions.
In Read-after-Conversion Mode, it should be noted that, unlike in other modes, the signal BUSY returns LOW after the 16 data bits are pulsed out and not at the end of the conversion phase, which results in a longer BUSY width.

## SLAVE SERIAL INTERFACE

## External Clock

The AD7664 is configured to accept an externally supplied serial data clock on the SCLK pin when the EXT/INT pin is held HIGH. In this mode, several methods can be used to read the data. The external serial clock is gated by $\overline{\mathrm{CS}}$. When $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ are both LOW, the data can be read after each conversion or during the following conversion. The external clock can be either a continuous or discontinuous clock. A discontinuous clock can be either normally HIGH or normally LOW, when inactive. Figures 18 and 20 show the detailed timing diagrams of these methods.
While the AD7664 is performing a bit decision, it is important that voltage transients not occur on digital input/output pins or degradation of the conversion result could occur. This is particularly important during the second half of the conversion phase, because the AD7664 provides error correction circuitry that can correct for an improper bit decision made during the first half of the conversion phase. For this reason, it is recommended that when an external clock is being provided, it is a discontinuous clock that is toggling only when BUSY is LOW or, more importantly, that it does not transition during the latter half of BUSY HIGH.

## External Discontinuous Clock Data Read after Conversion

 Though the maximum throughput cannot be achieved using this mode, it is the most often recommended of the serial Slave Modes. Figure 18 shows the detailed timing diagrams of this method. After a conversion is complete, indicated by BUSY returning LOW, the result of this conversion can be readwhile both $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ are LOW. The data is shifted out, MSB first, with 16 clock pulses and is valid on both the rising and falling edge of the clock.
Among the advantages of this method, the conversion performance is not degraded, because there are no voltage transients on the digital interface during the conversion process.
Another advantage is the ability to read the data at any speed up to 40 MHz , which accommodates both slow digital host interface and the fastest serial reading.
Finally, in this mode only, the AD7664 provides a daisy-chain feature using the RDC/SDIN input pin for cascading multiple converters together. This feature is useful for reducing component count and wiring connections when desired as, for instance, in isolated multiconverter applications.
An example of the concatenation of two devices is shown in Figure 19. Simultaneous sampling is possible by using a common $\overline{\text { CNVST }}$ signal. It should be noted that the RDC/SDIN input is latched on the edge of SCLK opposite to the one used to shift out the data on SDOUT. Therefore, the MSB of the upstream converter just follows the LSB of the downstream converter on the next SCLK cycle.

Figure 19. Two AD7664s in a Daisy-Chain Configuration

Figure 20. Slave Serial Data Timing for Reading (Read Previous Conversion during Convert)

## External Clock Data Read during Conversion

Figure 20 shows the detailed timing diagram of this method. During a conversion, while both $\overline{\mathrm{CS}}$ and $\overline{\mathrm{RD}}$ are LOW, the result of the previous conversion can be read. The data is shifted out MSB first with 16 clock pulses, and is valid on both the rising and falling edge of the clock. The 16 bits have to be read before the current conversion is complete; otherwise, RDERROR is pulsed HIGH and can be used to interrupt the host interface to prevent incomplete data reading. There is no daisy-chain feature in this mode and RDC/SDIN input should always be tied either HIGH or LOW.

To reduce performance degradation due to digital activity, a fast discontinuous clock of at least 18 MHz when in Impulse Mode, 25 MHz when in Normal Mode, or 40 MHz when in Warp Mode is recommended to ensure that all the bits are read during the first half of the conversion phase. It is also possible to begin to read the data after conversion and continue to read the last bits even after a new conversion has been initiated. That allows the use of a slower clock speed such as 14 MHz in Impulse Mode, 18 MHz in Normal Mode, and 25 MHz in Warp Mode.

## MICROPROCESSOR INTERFACING

The AD7664 is ideally suited for traditional dc measurement applications supporting a microprocessor and ac signal processing applications interfacing to a digital signal processor. The AD7664 is designed to interface either with a parallel 8 -bit or 16 -bit wide interface, or with a general-purpose serial port or I/O ports on a microcontroller. A variety of external buffers can be used with the AD7664 to prevent digital noise from coupling into the ADC. The following section discusses the use of an AD7664 with an ADSP-219x SPI equipped DSP.

## SPI Interface (ADSP-219x)

Figure 21 shows an interface diagram between the AD7664 and an SPI-equipped ADSP-219x. To accommodate the slower speed of the DSP, the AD7664 acts as a slave device and data must be read after conversion. This mode also allows the daisy-chain feature. The convert command can be initiated in response to an internal timer interrupt. The reading process can be initiated in response to the end-of-conversion signal (BUSY going LOW) using an interrupt line of the DSP. The serial interface (SPI) on the ADSP-219x is configured for master mode$(M S T R)=1$, Clock Polarity bit $(C P O L)=0$, Clock Phase bit $(\mathrm{CPHA})=1$, and SPI Interrupt Enable $($ TIMOD $)=00-$ by writing to the SPI control register (SPICLTx). To meet all timing requirements, the SPI clock should be limited to 17 Mbps, which allows it to read an ADC result in less than $1 \mu \mathrm{~s}$. When a higher sampling rate is desired, use of one of the parallel interface modes is recommended.

Figure 21. Interfacing the AD7664 to an SPI Interface

## APPLICATION HINTS

## Bipolar and Wider Input Ranges

In some applications, it is desired to use a bipolar or wider ana$\log$ input range like, for instance, $\pm 10 \mathrm{~V}, \pm 5 \mathrm{~V}$, or 0 V to 5 V . Although the AD7664 has only one unipolar range, by simple modifications of the input driver circuitry, bipolar and wider input ranges can be used without any performance degradation.
Figure 22 shows a connection diagram that allows this. Component values required and resulting full-scale ranges are shown in Table III.
For applications where accurate gain and offset are desired, they can be calibrated by acquiring a ground and a voltage reference using an analog multiplexer, U 2, as shown for bipolar input ranges in Figure 22.

Figure 22. Using the AD7664 in 16-Bit Bipolar and/or Wider Input Ranges

Table III. Component Values and Input Ranges

| Input Range | $\mathbf{R 1}(\mathbf{k} \boldsymbol{\Omega})$ | $\mathbf{R} \mathbf{( k \boldsymbol { \Omega } )}$ | $\mathbf{R} \mathbf{( k \boldsymbol { \Omega } )}$ | $\mathbf{R} \mathbf{( k \boldsymbol { \Omega } )}$ |
| :--- | :--- | :--- | :--- | :--- |
| $\pm 10 \mathrm{~V}$ | 1 | 8 | 10 | 8 |
| $\pm 5 \mathrm{~V}$ | 1 | 4 | 10 | 6.67 |
| 0 V to -5 V | 1 | 2 | None | 0 |

## Layout

The AD7664 has very good immunity to noise on the power supplies, as can be seen in Figure 9. However, care should still be taken with regard to grounding layout.
The printed circuit board that houses the AD7664 should be designed so that the analog and digital sections are separated and confined to certain areas of the board. This facilitates the use of ground planes that can be easily separated. Digital and analog ground planes should be joined in only one place, preferably underneath the AD7664, or, at least, as close as possible to the AD 7664 . If the AD 7664 is in a system where multiple devices require analog-to-digital ground connections, the connection should still be made at one point only, a star ground point that should be established as close as possible to the AD7664.

It is recommended to avoid running digital lines under the device, because these couple noise onto the die. The analog ground plane should be allowed to run under the AD7664 to avoid noise coupling. Fast switching signals like CNVST or clocks should be shielded with digital ground to avoid radiating noise to other sections of the board and should never run near analog signal paths. Crossover of digital and analog signals should be avoided. Traces on different but close layers of the board should run at right angles to each other. This reduces the effect of feedthrough through the board.
The power supplies' lines to the AD7664 should use as large a trace as possible to provide low impedance paths and reduce the effect of glitches on the power supplies' lines. Good decoupling is also important to lower the supplies' impedance presented to the AD7664 and to reduce the magnitude of the supply spikes. Decoupling ceramic capacitors, typically 100 nF , should be placed on each power supply's pins AVDD, DVDD, and OVDD close to, and ideally right up against, these pins and their corresponding ground pins. Additionally, low ESR $10 \mu \mathrm{~F}$ capacitors should be located in the vicinity of the ADC to further reduce low frequency ripple.
The DVDD supply of the AD7664 can be either a separate supply or come from the analog supply AVDD or the digital interface supply OVDD. When the system digital supply is noisy, or fast switching digital signals are present, it is recommended that, if no separate supply is available, to connect the DVDD digital supply to the analog supply, AVDD, through an RC filter, as shown in Figure 5, and to connect the system supply to the interface digital supply, OVDD, and the remaining digital circuitry. When DVDD is powered from the system supply, it is useful to insert a bead to further reduce high frequency spikes.
The AD7664 has five different ground pins: INGND, REFGND, AGND, DGND, and OGND. INGND is used to sense the analog input signal. REFGND senses the reference, voltage and should be a low impedance return to the reference because it carries pulsed currents. AGND is the ground to which most internal ADC analog signals are referenced. This ground must be connected with the least resistance to the analog ground plane. DGND must be tied to the analog or digital ground plane, depending on the configuration. OGND is connected to the digital system ground.

## Evaluating the AD7664 Performance

A recommended layout for the AD7664 is outlined in the EVAL-AD7664 evaluation board for the AD7664. The evaluation board package includes a fully assembled and tested evaluation board, documentation, and software for controlling the board from a PC via the EVAL-CONTROL-BRD2.
