

32-Channel, 16-Bit, Voltage-Output DACs with Serial Interface

General Description

The MAX5762–MAX5765 32-channel, 16-bit, voltage-output, digital-to-analog converters (DACs) are ideal for applications requiring a high number of programmable voltages. The MAX5762–MAX5765 can be programmed to calibrate the 16-bit input data word for gain and offset errors before updating the DAC output.

An SPI™-/QSPI™-/MICROWIRE™- or DSP-compatible serial interface controls the MAX5762–MAX5765. Each DAC channel has its own input, gain, and offset register. These three registers pass data through one of the two multiplier accumulator units (MACs), resulting in a voltage output corrected for gain and offset error. Each DAC channel has a double-buffered input structure to minimize the digital-noise feedthrough from the digital inputs to the outputs, and allows for synchronous or asynchronous updating of the outputs. The DAC outputs update independently or simultaneously with a single software or hardware command. The MAX5762–MAX5765 also provide a digital output (DOUT) that allows for readback or daisy chaining of multiple devices.

All DAC outputs are buffered and drive 10kΩ in parallel with 100pF. The MAX5762 has a 0 to +5V output range; the MAX5763 has a 0 to +10V output range; the MAX5764 has a -2.5V to +7.5V output range; and the MAX5765 has a -5V to +5V output range.

The MAX5762–MAX5765 are available in a 68-pin, 10mm x 10mm, TQFN package and a 64-pin, 12mm x 12mm, TQFP package. The MAX5762–MAX5765 are specified over the 0°C to +85°C temperature range. Refer to the MAX5732–MAX5735 data sheet for similar 16-bit, 32-channel DACs without offset and gain calibration.

Applications

- Automatic Test Systems
- Optical Router Controls
- Industrial Process Controls
- Arbitrary Function Generators
- Avionics Equipment
- Minimum Component Count Analog Systems
- Digital Offset/Gain Adjustment

Features

- ◆ Digital Offset and Gain Correction for Each DAC Channel
- ◆ Guaranteed Monotonic to 16 Bits
- ◆ 32 Individual DACs in a 10mm x 10mm, 68-Pin TQFN Package or 12mm x 12mm, 64-Pin TQFP Package
- ◆ Output Voltage Ranges
 - 0 to +5V (MAX5762)
 - 0 to +10V (MAX5763)
 - 2.5V to +7.5V (MAX5764)
 - 5V to +5V (MAX5765)
- ◆ Buffered Voltage Outputs Drive 10kΩ || 100pF
- ◆ Glitch-Free Power-Up
- ◆ SPI/QSPI/MICROWIRE- and DSP-Compatible 33MHz Serial Interface

Ordering Information

PART	PIN-PACKAGE	INL (LSB)	OUTPUT VOLTAGE RANGE (V)	PKG CODE
MAX5762AUTK**	68 TQFN-EP*	±8	0 to +5	T6800-3
MAX5762BUTK**	68 TQFN-EP*	±16	0 to +5	T6800-3

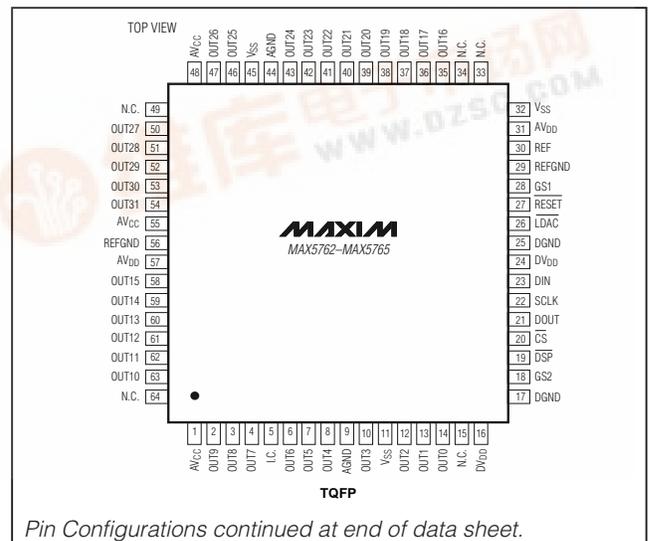

Ordering Information continued at end of data sheet.

Note: All devices are specified over the 0°C to +85°C temperature range.

*EP = Exposed paddle. Connect to VSS or leave unconnected.

**Future product—contact factory for availability.

Pin Configurations

Pin Configurations continued at end of data sheet.

ABSOLUTE MAXIMUM RATINGS

AV_{CC} to V_{SS}, AGND, DGND, REFGND-0.3V to +12V
 V_{SS} to AGND, DGND-6V to +0.3V
 AV_{DD} to AGND, DGND, REFGND-0.3V to +6V
 DV_{DD} to AGND, DGND, REFGND-0.3V to AV_{DD}
 AGND to DGND-0.3V to +0.3V
 REF to AGND,
 DGND, REFGND-0.3V to the lower of (AV_{DD} + 0.3V) and +6V
 REFGND to AGND-0.3V to +0.3V
 Digital Inputs to AGND, DGND,
 REFGND-0.3V to the lower of (DV_{DD} + 0.3V) and +6V
 DOUT to DGND-0.3V to the lower of (DV_{DD} + 0.3V) and +6V
 OUT₋ to V_{SS}-0.3V to the lower of (AV_{CC} + 0.3V) and +12V

GS1, GS2 to AGND-1V to +1V
 GS1, GS2 to V_{SS}-0.3V to +6V
 Maximum Current into REF±10mA
 Maximum Current into Any Other Pin±50mA
 Maximum Power Dissipation (T_A = +70°C)
 68-Pin TQFN (derate 50.0mW/°C above +70°C)4.0W
 64-Pin TQFP (derate 25.0mW/°C above +70°C)2.0W
 Operating Temperature Range0°C to +85°C
 Junction Temperature+150°C
 Storage Temperature Range-65°C to +150°C
 Lead Temperature (soldering, 10s)+300°C

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS—MAX5762 (0 to +5V Output Voltage Range)

Note 1: AV_{CC} should be at least 0.25V higher than the maximum output voltage required from the DAC.

Note 2: Linearity guaranteed for full code range.

Note 3: Offset error is measured at code 0. Gain error is measured at code FFFFh.

Note 4: DC crosstalk is the change in the output level of one DAC at midscale in response to the full-scale output change of all other DACs.

Note 5: Digital feedthrough is a measure of the impulse injected into the analog outputs from the digital control inputs when the device is not being written to. It is measured with a worst-case change on the digital inputs.

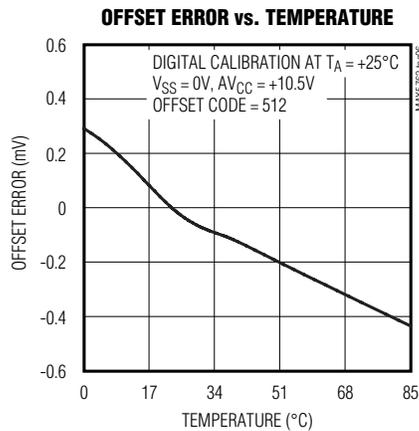

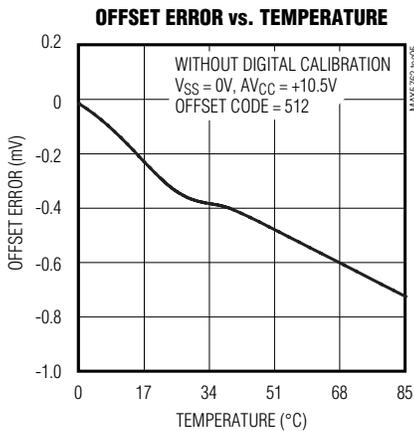

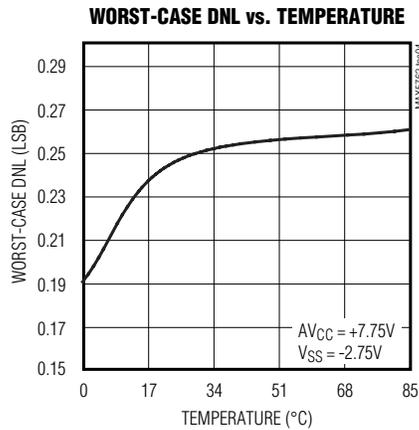

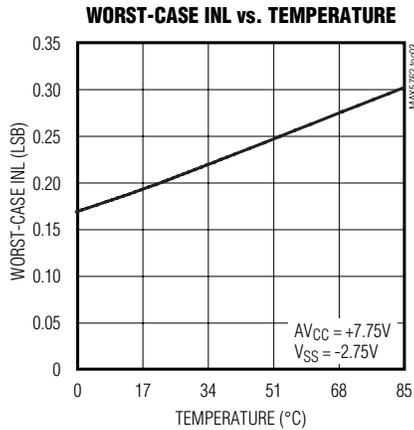

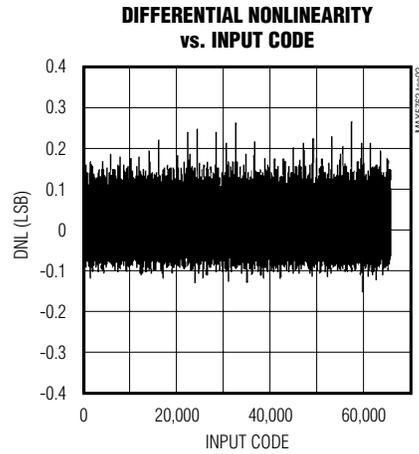

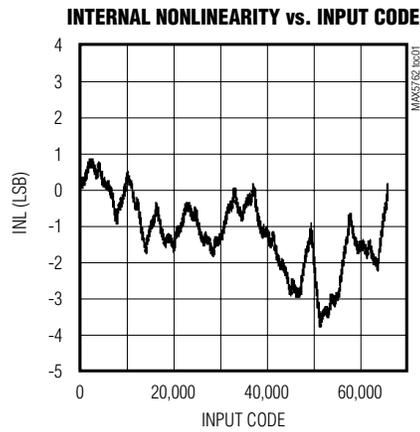

Note 6: DAC-to-DAC crosstalk is the glitch impulse that appears at the output of one converter due to both the digital change and subsequent analog output change at another converter.

Note 7: In DSP mode, maintain the maximum \overline{CS} pulse width low to ≤ 16 SCLK cycles.

32-Channel, 16-Bit, Voltage-Output DACs with Serial Interface

Detailed Description

The MAX5762–MAX5765 are 32-channel, 16-bit, voltage-output DACs. All devices accept a +3.0V external reference input at REF. An internal offset DAC allows all outputs to be offset up to -5V (see Table 1).

A 33MHz SPI-/QSPI-/MICROWIRE- or DSP-compatible serial interface (see Figure 1) controls the MAX5762–MAX5765. Use DSP to select the DSP mode or the SPI/QSPI/MICROWIRE mode.

Each DAC has a double-buffered input structure to minimize the digital-noise feedthrough from the digital inputs to the outputs. The two buffers are organized as an input register followed by a DAC register. Input registers update the DAC registers independently or simultaneously with a single software or hardware command. Each DAC channel has its own offset and gain registers that calibrate offset and gain errors for a given channel. The MAX5762–MAX5765 are divided into two banks of 16 channels to provide real-time calibration of channel pairs. Channel bank pairs are ordered as (bank 0:bank 1) OUT0:OUT16, OUT1:OUT17 ... OUT14:OUT30, OUT15:OUT31.

An offset DAC allows all the outputs to be offset up to -5V and dual ground-sensing inputs (GS1 and GS2) allow the output voltages to be referenced to remote grounds (see the *Functional Diagram*). Three output channels of each channel bank (bank 0 and bank 1) are referenced to GS2 (OUT0, OUT1, OUT2 in bank 0, and OUT16, OUT17, OUT18 in bank 1). All other output channels are referenced to GS1.

The MAX5762–MAX5765 analog and digital sections have separate power inputs (AVDD and DVDD). Separate power inputs are also provided for the output buffers (AVCC and VSS). Proprietary deglitch circuitry prevents output glitches at power-up and eliminates the need for power sequencing. A software-shutdown mode facilitates efficient power management. When shut down, the MAX5762–MAX5765 consume 50µA (typ) of supply current.

The MAX5762–MAX5765 have a 5µs (typ) wake-up time from shutdown mode to normal DAC operation.

All DACs provide buffered outputs that can drive 10kΩ in parallel with 100pF. The MAX5762 has a 0 to +5V output; the MAX5763 has a 0 to +10V output range; the MAX5764 has a -2.5V to +7.5V output range; and the MAX5765 has a -5V to +5V output range.

32-Channel, 16-Bit, Voltage-Output DACs with Serial Interface

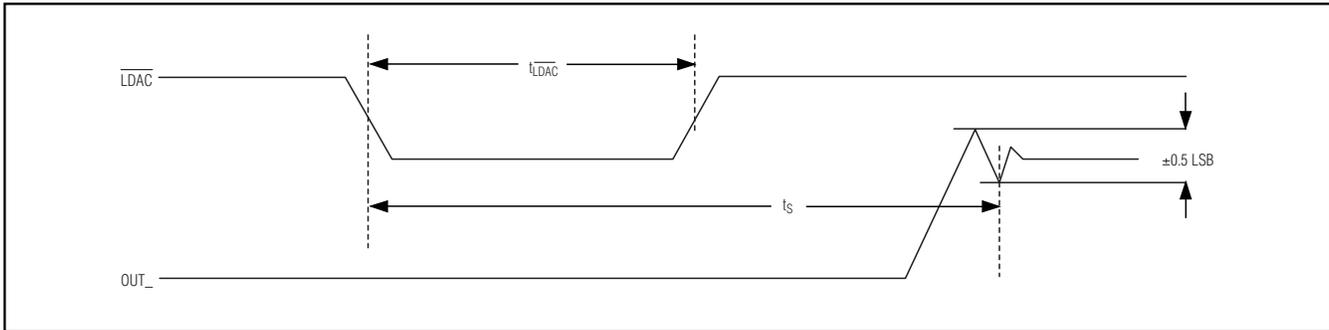

Figure 2. $\overline{\text{LDAC}}$ Timing

External Reference Input (REF)

The REF voltage sets the full-scale output voltage for all 32 DACs. REF accepts a $+3.0\text{V} \pm 3\%$ input. Reference voltages outside these limits result in a degradation of device performance.

REF is a buffered input. The input impedance is $1\text{M}\Omega$ minimum, and it does not vary with code. Use a high-accuracy, low-noise voltage reference such as the MAX6126AASA30 (3ppm/ $^{\circ}\text{C}$ temperature drift and 0.02% initial accuracy) to improve static accuracy. REF does not accept AC signals.

Ground Sense (GS1 and GS2)

The MAX5762-MAX5765 include ground-sense inputs (GS1 and GS2) that allow the output voltages to be referenced to a remote ground. The ground-sense input GS1 is connected to channels OUT3-OUT15 (bank 0) and to channels OUT19-OUT31 (bank 1). The ground-sense input GS2 is connected to channels OUT0, OUT1, OUT2 (bank 0), and OUT16, OUT17, OUT18 (bank 1). Channels connected to the same ground sense can be accessed in pairs. For example, OUT0 and OUT16 can be accessed as a pair (see Figure 3 for pairing of output channels).

The ground-sense input voltage range (V_{GS1} or V_{GS2}) is -0.5V to $+0.5\text{V}$ with respect to AGND. V_{GS} is added to the output voltage with unity gain. Ensure that the resulting output voltage is within the valid output voltage range set by the power supplies. See the *Output Amplifiers (OUT0-OUT31)* section for the effect of the ground-sense inputs on the DAC outputs.

Offset DAC

The MAX5762-MAX5765 feature an offset DAC that determines the output voltage range. While each device provides an allowable output voltage range, the offset DAC determines the end-point voltages of the range. Table 1 shows the offset DAC code necessary for each device's output voltage range.

The MAX5762-MAX5765 offset DAC can be programmed with any of the three output voltage ranges. The specifications in the *Electrical Characteristics* table are only guaranteed (production tested) for the offset code associated with each particular part number.

The offset DAC is summed with the GS_ input voltage (see the *Functional Diagram*). Any change in the offset DAC affects all 32 DACs.

The offset DAC is also double buffered with an input and DAC register.

Software commands for the MAC-bypass for all channels and load-DAC for all channels do not affect the offset DAC.

The data format for writing to the offset DAC is: control bits C3-C0 = 0011, address bits A5-A0 = 110000, 16 data bits, and 6 don't-care bits as shown in Table 2.

Table 2. Offset DAC Input Data Format

CONTROL BITS	ADDRESS BITS	DATA BITS	DON'T-CARE BITS

Figure 3. Address Space When Accessing DAC Channel Register(s), Offset Register(s), Gain Register(s), and Special Registers

32-Channel, 16-Bit, Voltage-Output DACs with Serial Interface

Output Amplifiers (OUT0-OUT31)

All DAC outputs are internally buffered. The internal buffers provide gain, improved load regulation, and glitch suppression for the DAC outputs. The output buffers slew at 1V/μs and can drive 10kΩ in parallel with 100pF. The output buffers are powered by AVCC and VSS. AVCC and VSS determine the maximum output voltage range of the device.

The input code, the voltage reference, the offset DAC output, the voltage on GS1 (or GS2), and the gain of the output amplifier determine the output voltage. Calculate VOUT as follows:

$$V_{OUT} = \frac{GAIN \times V_{REF} \times (DAC\ CODE - OFFSET\ DAC\ CODE)}{2^{16}} + V_{GS_}$$

where GAIN = 5/3 for the MAX5762 and GAIN = 10/3 for the MAX5763/MAX5764/MAX5765.

Load-DAC (LDAC) Input

The MAX5762-MAX5765 feature an active-low LDAC input that allows the outputs (OUT_) to update asynchronously. Keep LDAC high during normal operation (when the device is controlled only through the serial interface). Drive LDAC low to simultaneously update all DAC outputs with data from their respective input registers. Figure 2 shows the LDAC timing with respect to OUT_.

A software command can also perform the LDAC operation. To initiate LDAC by software, set control bits C3-C0 = 0010, address bits A5-A0 = 111111, and all data bits to don't care. See Table 3 for the data format. This operation updates all DAC outputs simultaneously. The software load-DAC command for all channels does not affect the offset DAC.

Software MAC-Bypass

The MAX5762-MAX5765 feature a software MAC-bypass command that loads data into the DAC directly from DIN. Software MAC-bypass loads one DAC, a pair of DACs, or all 32 DACs with a data word (D15-D0) entered at DIN and the selected DAC output(s) are simultaneously updated. Software MAC-bypass bypasses gain and offset calibration, sending the input data directly to the DAC register immediately updating the selected DAC outputs. After executing MAC-bypass on a channel(s), previously calibrated data can be reloaded into the DAC by executing software load-DAC or hardware LDAC (see Figure 4). Using software MAC-bypass, the DAC output(s) can be set to the ground-sense value or any arbitrary value within the DAC output voltage range.

To activate software MAC-bypass, set control bits C3-C0 = 0111. The address bits (A5-A0) select the

DAC(s) to be updated, and the data bits (D15-D0) control the DAC output-voltage value. Table 4 shows the input data format for the software-controlled MAC-bypass command.

Reset (RESET)

The MAX5762-MAX5765 feature an active-low RESET logic input that asynchronously sets all the registers to code 0000h (power-up state). The serial interface can also issue a software-reset command. Setting the control bits C3-C0 = 1111 performs the same function as driving the logic input RESET low. Table 5 shows the reset data format for the software-controlled reset command. The software reset does not work in daisy-chain mode. Reprogram the offset DAC after asserting a software or hardware reset.

Serial Interface

The MAX5762-MAX5765 allow channel updates either individually or in pairs. This is achieved by dividing the 32 channels into two channel banks, with 16 channels in each bank. Channel bank 0 contains output channels OUT0-OUT15, and channel bank 1 contains channels OUT16-OUT31. A channel from bank 0 is paired with a channel from bank 1 and is ordered as OUT0:OUT16, OUT1:OUT17...OUT14:OUT30, OUT15:OUT31.

A 3-wire SPI-/QSPI-/MICROWIRE- and DSP-compatible serial interface controls the MAX5762–MAX5765. The interface requires a 32-bit command word to control the device. The command word consists of 4 control bits, 6 address bits, 16 data bits, and 6 don't-care bits. Table 6 shows the general serial data format. The control bits control various write and read commands, as well as the load DAC and MAC-bypass commands. Table 8 shows the control-bit functions. The address bits select the register(s) to update. Figure 3 shows the address functions. The data bits control the voltage value of the DAC outputs. DIN data is clocked in at the falling edge of SCLK (Figure 1).

Table 8. Control-Bit Functions

4 CONTROL BITS				CONTROL-BIT DESCRIPTION
C3	C2	C1	C0	
0	0	0	0	No operation (NOP). No internal registers change state. The NOP command can be passed to DOUT depending on the state of the configuration register. Address bits A5–A0 and data bits D15–D0 are ignored.
0	0	0	1	This instruction writes and calibrates the 16-bit input data word for gain and offset errors. Drive LDAC low or use a software load-DAC command to update the selected DAC outputs.
0	0	1	0	Software load-DAC command. Updates the output of the selected DAC channel(s). Depending on the address bits, this command updates one DAC output, a pair of DAC outputs, or all the DAC outputs simultaneously. Data bits D15–D0 are ignored.
0	0	1	1	This instruction writes and calibrates the 16-bit input data word for gain and offset errors and immediately updates the DAC outputs for the selected address.
0	1	0	0	Read command. Depending on the address bits, one of the input register values is read back through DOUT. Data bits D15–D0 are ignored. See the <i>Daisy-Chain Operation</i> section.
0	1	0	1	Reserved; do not use.
0	1	1	0	Reserved; do not use.
0	1	1	1	MAC-bypass command. Depending on the address bits, one, two, or all DAC registers are loaded with a 16-bit data word at DIN. The input data is not calibrated for gain and offset errors (see the <i>Software MAC-Bypass</i> section). Selected DAC output(s) are immediately updated.
1	0	0	0	Loads D15–D0 into one or two of the gain register(s) for the selected address. The data for the selected address is calibrated for gain error. Drive LDAC low or use a software load-DAC command to update the selected DAC outputs.
1	0	0	1	Loads D15–D0 into one or two of the offset register(s) for the selected address. The data for the selected address is calibrated for offset error. Drive LDAC low or use a software load-DAC command to update the selected DAC outputs.
1	0	1	0	Read command. Reads one of the gain registers and presents the data at DOUT.
1	0	1	1	Read command. Reads one of the offset registers and presents the data at DOUT.
1	1	0	0	Write command. Loads D15–D0 into the configuration register.
1	1	0	1	Read command. Reads the contents of the configuration register.
1	1	1	0	Read command. Reads the DAC register for the selected address.
1	1	1	1	Reset instruction.

32-Channel, 16-Bit, Voltage-Output DACs with Serial Interface

Gain and Offset Registers

The MAX5762–MAX5765 contain a gain and offset register associated with each channel to correct real-time gain and offset errors associated with each channel. The gain and offset registers can be accessed individually or in pairs.

The gain word range is limited between 0 and 1. The gain word is an unsigned 16-bit data word. A gain word of 0000h is a special mapping to provide a gain of absolute one, i.e., no gain correction. For all the other gain word codes, the amount of gain correction varies proportionally to the gain word's decimal value. For

example, a gain word of 0001h is equivalent to a gain of 0.5^{16} and a gain of FFFFh is equivalent to $1 - 0.5^{16}$ (see Table 9). To access the gain register, set control bits C3–C0 = 1000 (see Tables 7 and 8).

The offset has a range from $-FS/2$ to $+(FS/2 - 1 \text{ LSB})$. The offset word is a 16-bit data word represented in two's complement. For example, an offset word equivalent to 7FFFh would provide an offset of $FS/2 - 1 \text{ LSB}$ and offset word of 8000h would provide an offset of $-FS/2$ (see Table 10). To access the offset register, set control bits C3–C0 = 1001 (see Tables 7 and 8).

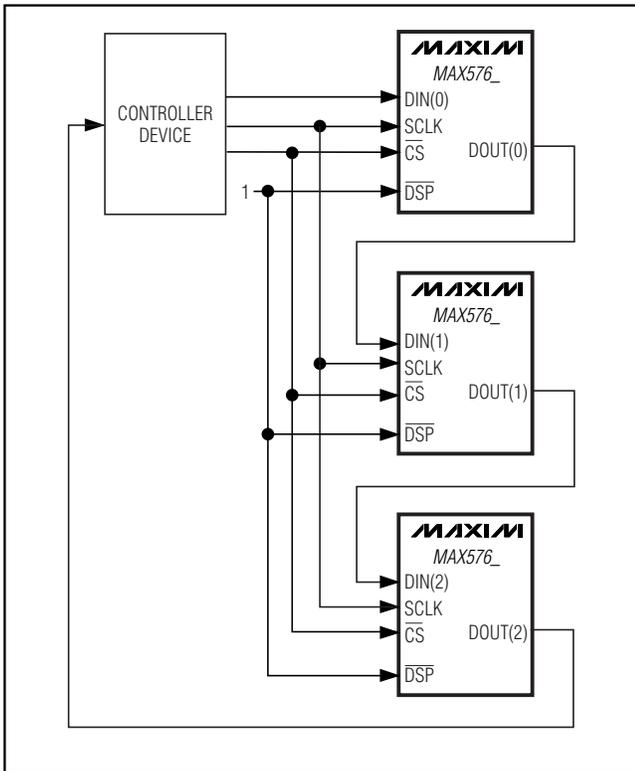

Figure 5. Daisy-Chain Configuration

Table 9. Gain Register Code Values

CODE (DATA BITS D15–D0)	GAIN VALUE
0000h	Unity gain
0001h	0.00001526
0002h	0.00003052
...	...
7FFFh	0.49998474
8000h	0.5
...	...
FFFEh	0.99996948
FFFFh	0.99998474

Table 10. Offset Register Code Values

CODE (DATA BITS D15–D0)	OFFSET VALUE*
7FFFh	$FS/2 - 1 \text{ LSB}$

8001h	$-FS/2 + 1 \text{ LSB}$
8000h	$-FS/2$

*1 LSB = $FS/2^{16}$

32-Channel, 16-Bit, Voltage-Output DACs with Serial Interface

Configuration Register

The configuration register controls the advanced features of the MAX5762–MAX5765. Write to the configuration register by setting control bits C3–C0 = 1100 and address bits 000000. Table 11 shows the configuration register data format for the D15–D0 data bits. Table 12 shows the commands controlled by the configuration register.

DSP Mode ($\overline{\text{DSP}}$)

The MAX5762–MAX5765 provide a hardware-selectable DSP-interface mode. The active-low $\overline{\text{DSP}}$ logic input selects the microcontroller (μC)-interface or DSP-interface mode. Drive $\overline{\text{DSP}}$ high for μC -interface mode. Drive $\overline{\text{DSP}}$ low for DSP-interface mode. DSP mode, when active, allows chip select ($\overline{\text{CS}}$) to go high before the entire 32-bit command word is clocked in. Figure 1 illustrates serial timing for both μC - and DSP-interface modes.

Table 11. Configuration Register Data Format

16 DATA BITS															
D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
ERRF	SING	GLT	DT	SHDN	X	X	X	X	X	X	X	X	X	X	X

X = Don't care.

Table 12. Configuration Register Commands

DATA BIT	NAME	DESCRIPTION
D15	ERRF	Error flag. ERRF goes logic-high when an invalid command is attempted. ERRF is cleared each time the configuration register is read back to DOUT. Reset-register commands C3–C0 = 1111 reset ERRF. Conditions that trigger ERRF include: <ul style="list-style-type: none"> • Attempted read of a wrong or invalid address bits A5–A0 • Access to reserved addresses The default is logic-low (no error flags); ERRF is read only.
D14	SING	Single device. SING determines daisy-chain or stand-alone mode. Logic-high sets the device to operate in stand-alone mode or in parallel with other devices. Only 16 data bits are output to DOUT when SING is logic-high. When SING is logic-low, the entire 32-bit command word is output to DOUT. The default is logic low (daisy-chain mode). For daisy-chain operation, set SING to logic-low and $\overline{\text{DSP}}$ must be set high (μC mode). SING is read/write.
D13	GLT	Glitch-suppression enable. The MAX5762–MAX5765 feature glitch-suppression circuitry on the analog outputs that minimizes the output glitch during a major carry transition. A logic-low disables the internal glitch-suppression circuitry. Logic-high enables glitch suppression, suppressing up to a 120nV-s glitch impulse on the DAC outputs. Default is logic-low (glitch suppression is disabled). GLT is read/write.
D12	DT	Digital output enable. A logic-low enables DOUT. Logic-high disables DOUT. Disabling DOUT reduces power consumption and digital noise feedthrough to the DAC outputs from the DOUT output buffer. Default is logic-low (DOUT enabled); DT is read/write.
D11	SHDN	Shutdown. A logic-high shuts down all 32 DACs. The logic interface remains active, and the data is retained in the DAC and input registers. Read/write operations can be performed while the device is shut down; however, no changes can occur at the device outputs. Logic-low powers up all 32 DACs. Upon waking up (5 μs (typ)), the DAC outputs return to the last stored value in the DAC registers. Default is logic-low (normal operation). SHDN is read/write.
D10–D0	X	Don't care.

32-Channel, 16-Bit, Voltage-Output DACs with Serial Interface

SING

When SING = 0, the MAX5762-MAX5765 are in daisy-chain mode. For daisy-chain operation, set DSP high (μC mode) and SING = 0.

In daisy-chain operation, DOUT follows DIN after 32 clock cycles for a write command. For a read command, DOUT provides only the 16 data bits in the next cycle following the CS falling edge. Data is provided MSB first at DOUT on the falling edge of SCLK.

When SING = 1, the device is in stand-alone mode. To reduce the time it takes to read data out, the read data is provided MSB first at DOUT on the last 16 cycles of the current command word. The device acts on an

incoming command word independent of the rising edge of CS. SING functionality is ignored in DSP mode.

Daisy-Chain Operation

Daisy chain any number of the MAX5762-MAX5765 devices by connecting the DOUT of one device to the DIN of another. Set DSP high and SING = 0 for all devices in the daisy chain (see Figure 5).

The MAX5762-MAX5765 support daisy-chain connections of multiple devices. The default (power-up) configuration for the MAX5762-MAX5765 assumes that the device may be part of a daisy chain of devices (SING = 0 and DSP = 1). For a write command, DOUT follows DIN after 32 clock cycles in the default configuration. Figures 6 and 7 show examples of daisy-chain data sequences.

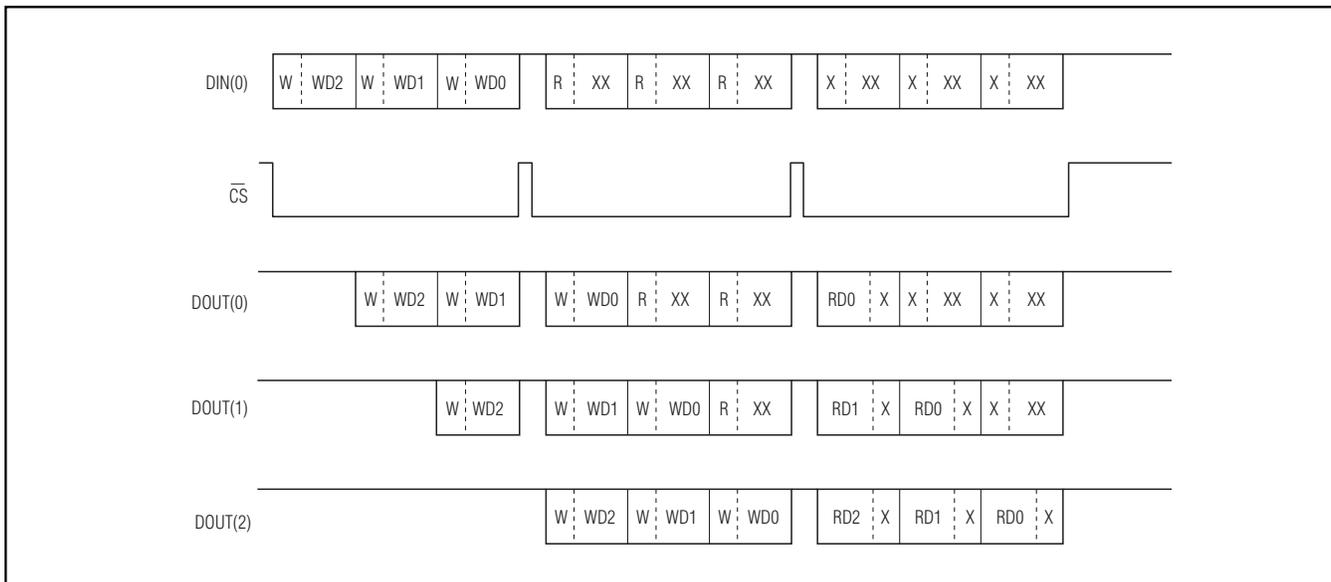

Figure 6. Example 1 of a Daisy-Chain Data Sequence

W/WD0 = 32-bit word with a write command; WD0 writes data for device 0. The 0 refers to the position in the daisy chain (0 is closest to the bus master). Devices 1 and 2 are devices further down the chain.

RDn/X = 32-bit word with a 16-bit read output from device n followed by don't-care bits.

X = Don't care (for X in the data or command position).

32-Channel, 16-Bit, Voltage-Output DACs with Serial Interface

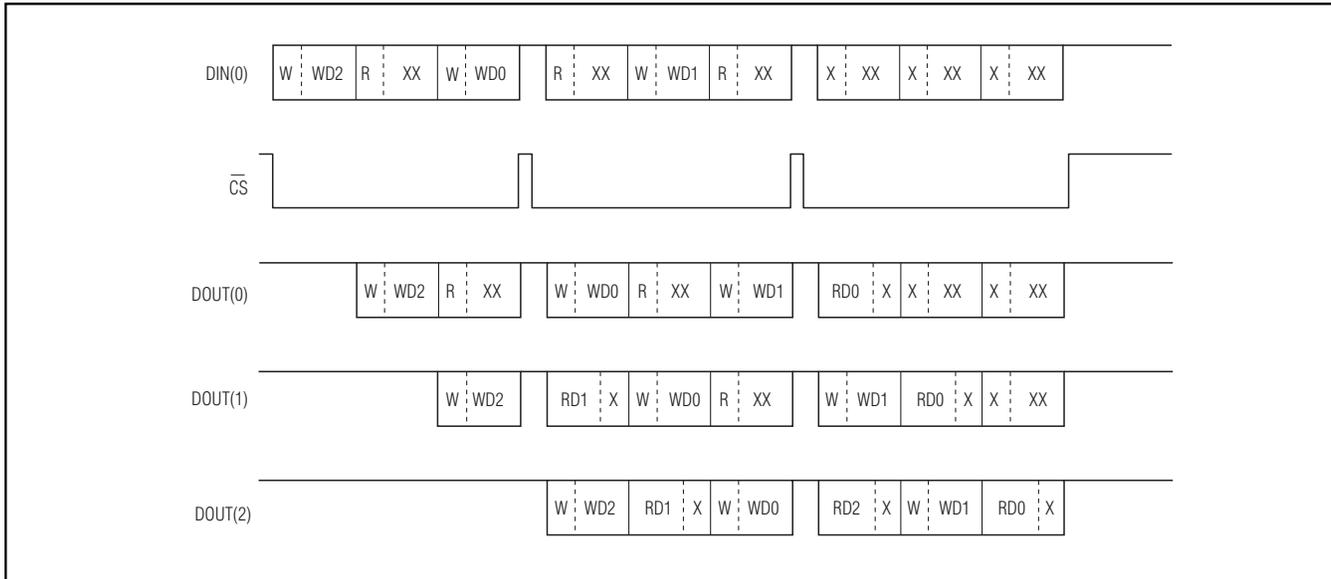

Figure 7. Example 2 of a Daisy-Chain Data Sequence

W/WD0 = 32-bit word with a write command; WD0 writes data for device 0. The 0 refers to the position in the daisy chain (0 is closest to the bus master). Devices 1 and 2 are devices further down the chain.

RDn/X = 32-bit word with a 16-bit read output from device n followed by don't-care bits.

X = Don't care (for X in the data or command position).

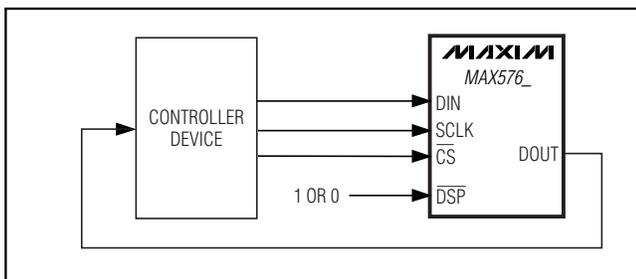

Figure 8. Stand-Alone Configuration

Data Readback

Read the contents of the MAX5762–MAX5765 DAC and configuration registers at DOUT by issuing a read-data command. Control bits C3–C0 configure the device for the read-data modes (see Table 8). The address bits

select the register(s) to be read. The contents of the register(s) are clocked out MSB first at DOUT on the falling edge of SCLK. The output data format depends on the status of $\overline{\text{DSP}}$ and SING. Table 13 shows the manner in which data is written to DOUT.

Shutdown Mode

The MAX5762–MAX5765 feature a software-controlled, low-power shutdown mode.

Setting bit 9 of the configuration register to a logic-high disables the analog section of the device, forcing the outputs to go high impedance. In shutdown, supply current is reduced to 50µA typical. Data stored in the DAC and input registers is retained, and the device outputs return to their previous values upon exiting shutdown. Wake-up time is 5µs (typ). The serial interface remains active while the device is in shutdown.

32-Channel, 16-Bit, Voltage-Output DACs with Serial Interface

Table 13. Read-Data Modes with SING and $\overline{\text{DSP}}$ Controls

DSP	SING	CONFIGURATION	READ DATA AT DOUT
0	X	Stand-alone DSP mode	DOUT provides the 16 data bits only. The 16 data bits are clocked out MSB first at DOUT, on the last 16 clock edges of the current read command word. See Figures 8, 9, and 10.
1	0	Standard daisy-chain configuration μC mode	For write commands, DOUT follows DIN after 32 clocks. The entire 32-bit write command word (both command word and data) is clocked out MSB first at DOUT. For read commands, the 16 data bits of the selected register are valid at DOUT starting with the first clock falling edge after the falling edge of $\overline{\text{CS}}$. See Figures 6 and 7.
1	1	Stand-alone μC mode	DOUT provides the 16 data bits of the selected register from the current read command word. The 16 data bits are clocked out MSB first at DOUT on the last 16 clock edges of the current read command word. See Figures 8, 9, and 10.

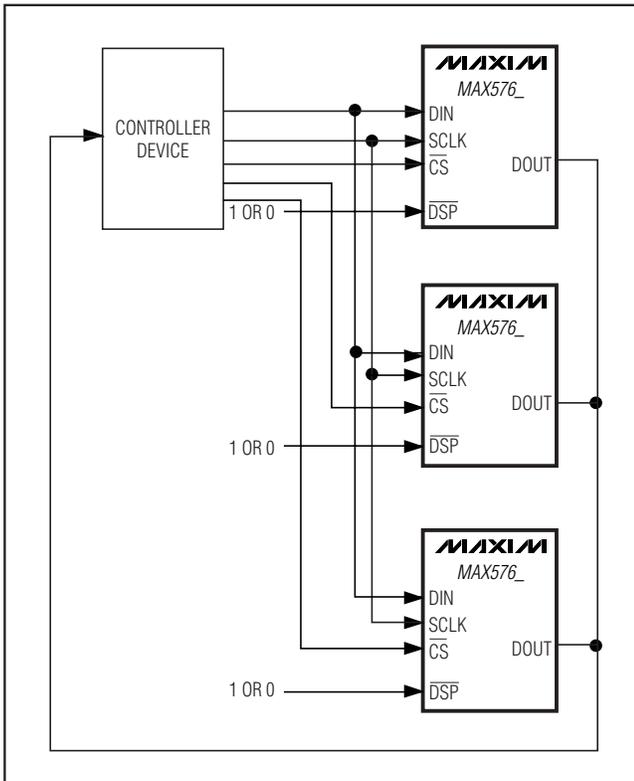

Figure 9. Example of a Parallel Configuration with Readback

Power-Up State

The MAX5762-MAX5765 monitor the four power supplies and maintain the output buffers in a known state until sufficient voltage is available to ensure that no output glitches occur. Once the minimum voltage threshold has been exceeded, the device outputs come up in the clear state (all outputs = 0).

Applications Information

Automatic Test Equipment (ATE) Applications

The MAX5762-MAX5765 include many features suited for ATE applications. These devices are the most highly integrated level-setting solution available for high-density pin electronics boards, and provide the output voltage ranges required by most ATE applications. The offset DAC simultaneously adjusts the voltage range of all 32 DACs, allowing optimization to the application. The remote-sense feature (GS1 and GS2) allows the pin electronic voltages to be referenced to the ground potential at the DUT site. An integrated offset and gain feature eliminates the need for costly external circuitry.

The pipelined register architecture allows all 32 DACs to be updated simultaneously. This is valuable during test setups, as all values in the tester can be set and then updated in unison with a single command. Accessing the serial interface or the LDAC input updates all 32 DACs simultaneously.

32-Channel, 16-Bit, Voltage-Output DACs with Serial Interface

MAX5762-MAX5765

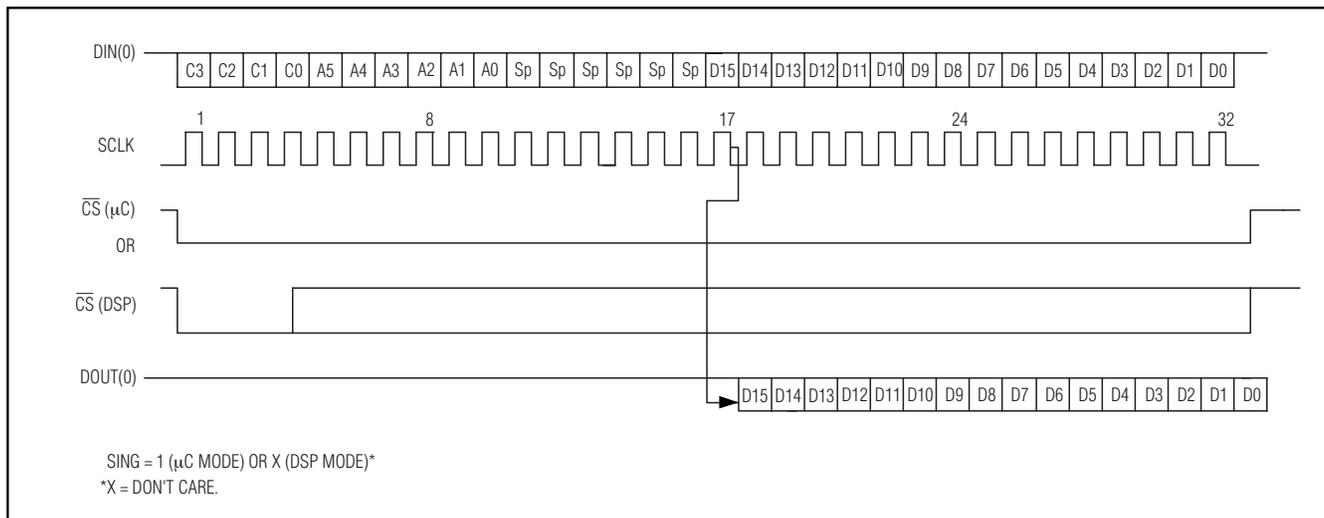

Figure 10. Read Data Timing When Not Daisy Chained

The low output noise of the MAX5762–MAX5765 allows direct connection to the pin electronics, eliminating the cost and PC board area of external filtering.

Modern pin electronics integrated circuits (PEICs) are typically fabricated on high-speed processes with low breakdown voltages. Some devices require external protection on their reference inputs to satisfy absolute maximum ratings. The MAX5762–MAX5765 feature outputs that are almost rail-to-rail allowing the AV_{CC} and V_{SS} supplies to be set to voltages within the absolute maximum ratings of the PEIC to guarantee that the PEIC is protected in all situations.

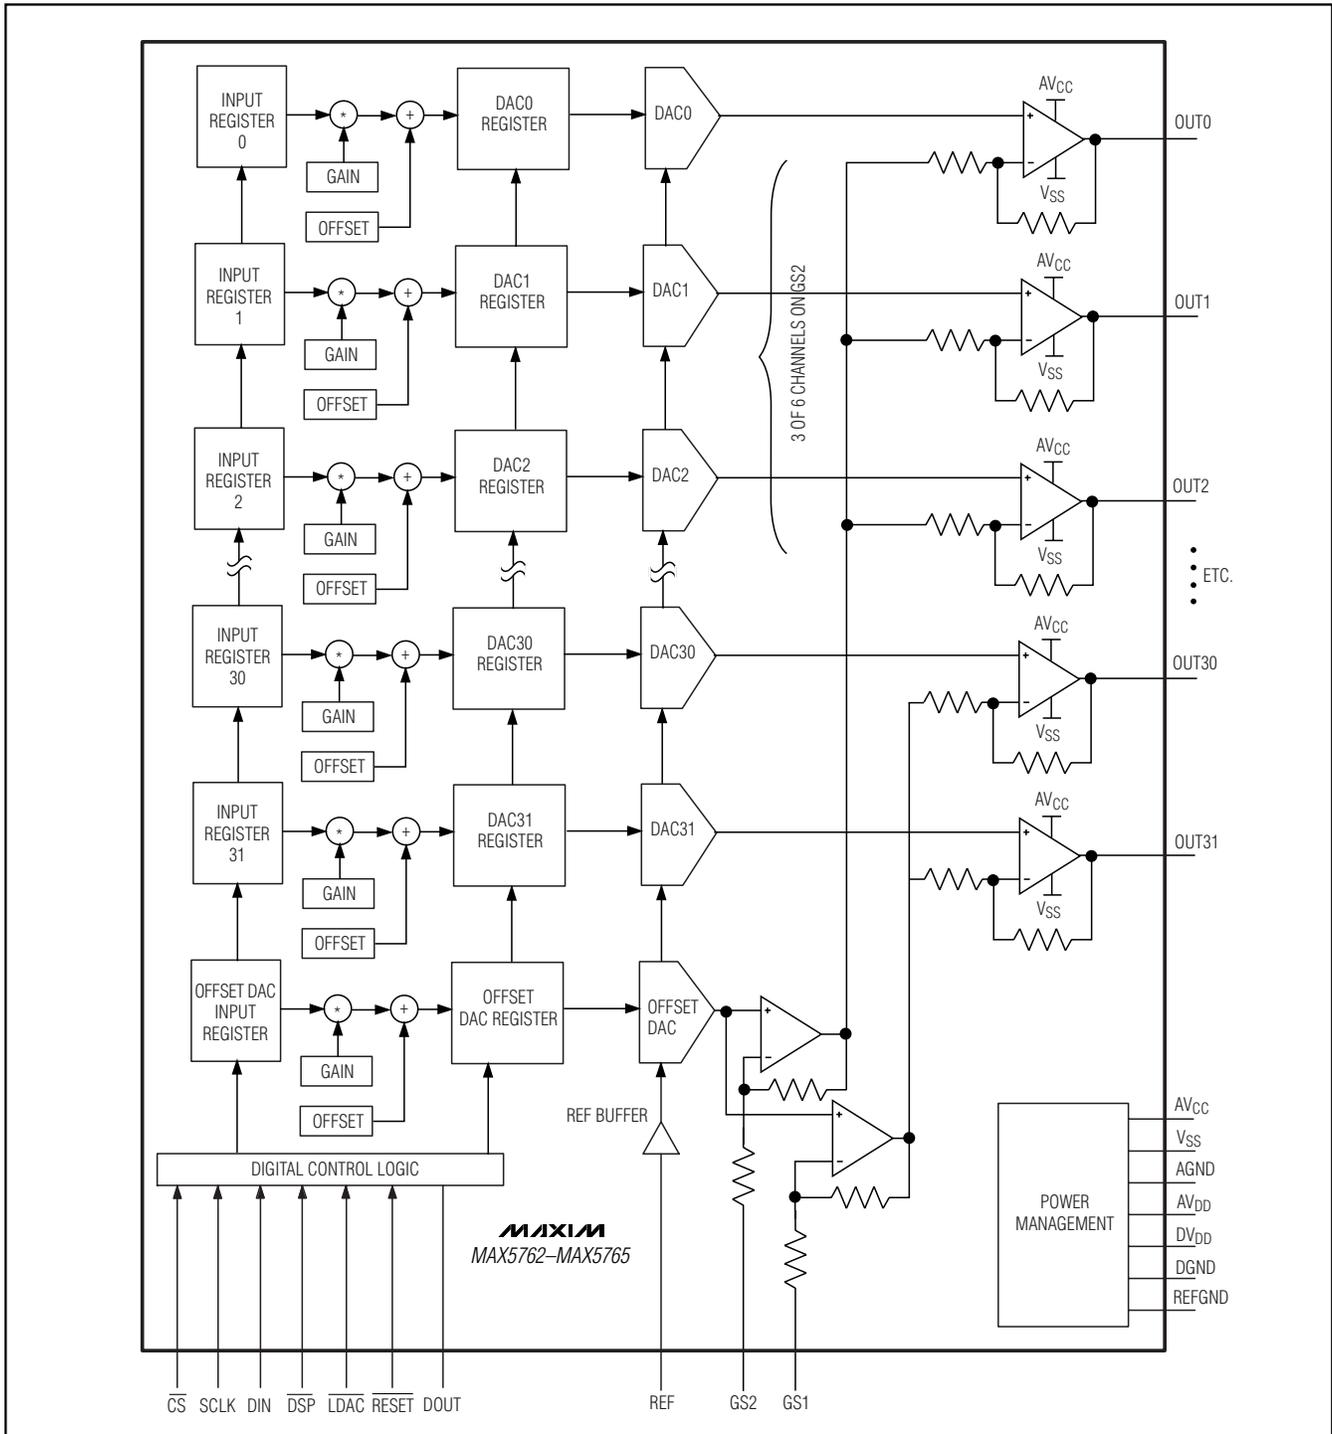

Power Supplies, Bypassing, Decoupling, and Layout

Grounding and power-supply decoupling strongly influence device performance. Digital signals can couple through the reference input, power supplies, and ground connection. Proper grounding and layout can reduce digital feedthrough and crosstalk. For noisy environments, bypass all power supplies with 0.1 μ F and 1 μ F on each pin, as close to the device as possible.

The MAX5762–MAX5765 have four separate power supplies. AV_{DD} powers the internal analog circuitry (except for the output buffers), and DV_{DD} powers the digital section of the device. AV_{CC} and V_{SS} power the output buffers.
