## FEATURES

Low Power
1 mA Supply Current／Amp
High Speed
$350 \mathrm{MHz},-3 \mathrm{~dB}$ Bandwidth（ $\mathrm{G}=+1$ ）
425 V／us Slew Rate

## Low Cost

Low Noise
$8 \mathrm{nV} / \sqrt{\mathrm{Hz}}$＠ 100 kHz
$600 \mathrm{fA} / \sqrt{\mathrm{Hz}}$＠ 100 kHz
Low Input Bias Current： 750 nA Max
Low Distortion
－90 dB SFDR＠ 1 MHz
-65 dB SFDR＠ 5 MHz
Wide Supply Range： 3 V to 12 V
Small Packaging：SOT23－8，SC70－5，and SOIC－8

## APPLICATIONS

Battery－Powered Instrumentation
Filters
A／D Driver
Level Shifting
Buffering
High Density PC Boards
Photo Multiplier

## PRODUCT DESCRIPTION

The AD8038（single）and AD8039（dual）amplifiers are high speed（ 350 MHz ）voltage feedback amplifiers with an exceptionally low quiescent current of $1.0 \mathrm{~mA} /$ amplifier typical（ 1.5 mA max）． The AD8038 single amplifier in the SOIC－8 package has a disable feature．Despite being low power and low cost，the amplifier provides excellent overall performance．Additionally， it offers a high slew rate of $425 \mathrm{~V} / \mu \mathrm{s}$ and low input offset volt－ age of 3 mV max．
ADI＇s proprietary XFCB process allows low noise operation $(8 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ and $600 \mathrm{fA} / \sqrt{\mathrm{Hz}}$ ）at extremely low quiescent currents． Given a wide supply voltage range（ 3 V to 12 V ），wide bandwidth， and small packaging，the AD8038 and AD8039 amplifiers are designed to work in a variety of applications where power and space are at a premium．
The AD8038 and AD8039 amplifiers have a wide input common－ mode range of 1 V from either rail and will swing within 1 V of each rail on the output．These amplifiers are optimized for driving capacitive loads up to 15 pF ．If driving larger capaci－ tive loads，a small series resistor is needed to avoid excessive peaking or overshoot．
＊Not yet released

## CONNECTION DIAGRAMS

SOIC－8（R）

SOIC－8（R）and SOT23－8（RT）＊

The AD8039 amplifier is the only dual low power，high speed amplifier available in a tiny SOT23－8 package，and the single AD8038 is available in both a SOIC－8 and a SC70－5 package． These amps are rated to work over the industrial temperature range of $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ ．

## AD8038/AD8039

#### Abstract

ABSOLUTE MAXIMUM RATINGS* Supply Voltage 12.6 V

Power Dissipation See Figure 2 Common-Mode Input Voltage . . . . . . . . . . . . . . . . . . . . $\pm \mathrm{V}_{\text {S }}$ Differential Input Voltage . . . . . . . . . . . . . . . . . . . . . . . . $\pm 4 \mathrm{~V}$ Storage Temperature . . . . . . . . . . . . . . . . . $-65^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ Operating Temperature Range . . . . . . . . . . $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ Lead Temperature Range (Soldering 10 sec ) . . . . . . . . $300^{\circ} \mathrm{C}$ *Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## MAXIMUM POWER DISSIPATION

The maximum safe power dissipation in the AD8038/AD8039 package is limited by the associated rise in junction temperature $\left(T_{J}\right)$ on the die. The plastic encapsulating the die will locally reach the junction temperature. At approximately $150^{\circ} \mathrm{C}$, which is the glass transition temperature, the plastic will change its properties. Even temporarily exceeding this temperature limit may change the stresses that the package exerts on the die, permanently shifting the parametric performance of the AD8038/AD8039. Exceeding a junction temperature of $175^{\circ} \mathrm{C}$ for an extended period of time can result in changes in the silicon devices, potentially causing failure.
The still-air thermal properties of the package and $\operatorname{PCB}\left(\theta_{J A}\right)$, ambient temperature $\left(T_{A}\right)$, and total power dissipated in the package $\left(P_{D}\right)$ determine the junction temperature of the die. The junction temperature can be calculated as follows:

$$
T_{J}=T_{A}+\left(P_{D} \times \theta_{J A}\right)
$$

The power dissipated in the package $\left(P_{D}\right)$ is the sum of the quiescent power dissipation and the power dissipated in the package due to the load drive for all outputs. The quiescent power is the voltage between the supply pins $\left(\mathrm{V}_{\mathrm{S}}\right)$ multiplied by the quiescent current $\left(\mathrm{I}_{\mathrm{S}}\right)$. Assuming the load $\left(\mathrm{R}_{\mathrm{L}}\right)$ is referenced to midsupply, then the total drive power is $\mathrm{V}_{\mathrm{S}} / 2 \times \mathrm{I}_{\mathrm{OUT}}$, some of which is dissipated in the package and some in the load $\left(\mathrm{V}_{\text {OUT }} \times \mathrm{I}_{\text {OUT }}\right)$. The difference between the total drive power and the load power is the drive power dissipated in the package.
$P_{D}=$ quiescent power + (total drive power - load power)

$$
P_{D}=\left[V_{S} \times I_{S}\right]+\left[\left(V_{S} / 2\right) \times\left(V_{\text {OUT }} / R_{L}\right)\right]-\left[V_{O U T}^{2} / R_{L}\right]
$$

Figure 2. Maximum Power Dissipation vs. Temperature for a Four-Layer Board

RMS output voltages should be considered. If $\mathrm{R}_{\mathrm{L}}$ is referenced to $\mathrm{V}_{\mathrm{S}}$, as in single-supply operation, then the total drive power is $\mathrm{V}_{\mathrm{S}} \times \mathrm{I}_{\text {OUT }}$.
If the RMS signal levels are indeterminate, then consider the worst case, when $V_{\text {OUT }}=V_{S} / 4$ for $R_{L}$ to midsupply:

$$
P_{D}=\left(V_{S} \times I_{S}\right)+\left(V_{S} / 4\right)^{2} / R_{L}
$$

In single-supply operation with $R_{L}$ referenced to $V_{S \rightarrow}$, worst case is $\mathrm{V}_{\text {OUT }}=\mathrm{V}_{\mathrm{S}} / 2$.
Airflow will increase heat dissipation effectively reducing $\theta_{\mathrm{JA}}$. Also, more metal directly in contact with the package leads from metal traces, through holes, ground, and power planes, will reduce the $\theta_{\mathrm{JA}}$. Care must be taken to minimize parasitic capacitances at the input leads of high speed op amps as discussed in the board layout section.
Figure 2 shows the maximum safe power dissipation in the package versus the ambient temperature for the SOIC-8 $\left(125^{\circ} \mathrm{C} / \mathrm{W}\right)$, SC70-5 $\left(210^{\circ} \mathrm{C} / \mathrm{W}\right)$, and SOT23-8 $\left(160^{\circ} \mathrm{C} / \mathrm{W}\right)$ package on a JEDEC standard four-layer board. $\theta_{\mathrm{JA}}$ values are approximations.

## OUTPUT SHORT CIRCUIT

Shorting the output to ground or drawing excessive current from the AD8038/AD8039 will likely cause a catastrophic failure.

ORDERING GUIDE

[^1]
## CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD8038/AD8039 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## LAYOUT, GROUNDING, AND BYPASSING CONSIDERATIONS

## Disable

The AD8038 in the SOIC-8 package provides a disable feature. This feature disables the input from the output (see TPC 37 for input-output isolation) and reduces the quiescent current from typically 1 mA to 0.2 mA . When the DISABLE node is pulled below 4.5 V from the positive supply rail, the part becomes disabled. In order to enable the part, the $\overline{\text { DISABLE }}$ node needs to be pulled up to above 2.5 V below the positive rail.

## Power Supply Bypassing

Power supply pins are actually inputs, and care must be taken so that a noise-free stable dc voltage is applied. The purpose of bypass capacitors is to create low impedances from the supply to ground at all frequencies, thereby shunting or filtering a majority of the noise.
Decoupling schemes are designed to minimize the bypassing impedance at all frequencies with a parallel combination of capacitors. $0.01 \mu \mathrm{~F}$ or $0.001 \mu \mathrm{~F}$ (X7R or NPO) chip capacitors are critical and should be as close as possible to the amplifier package. Larger chip capacitors, such as the $0.1 \mu \mathrm{~F}$ capacitor, can be shared among a few closely spaced active components in the same signal path. A $10 \mu \mathrm{~F}$ tantalum capacitor is less critical for high frequency bypassing and, in most cases, only one per board is needed at the supply inputs.

## Grounding

A ground plane layer is important in densely packed PC boards to spread the current minimizing parasitic inductances. However, an understanding of where the current flows in a circuit is critical to implementing effective high speed circuit design. The length of the current path is directly proportional to the magnitude of parasitic inductances, and thus the high frequency impedance of the path. High speed currents in an inductive ground return will create an unwanted voltage noise.
The length of the high frequency bypass capacitor leads are most critical. A parasitic inductance in the bypass grounding will work against the low impedance created by the bypass capacitor. Place the ground leads of the bypass capacitors at the same physical location. Because load currents flow from the supplies as well, the ground for the load impedance should be at the same physical location as the bypass capacitor grounds. For the larger value capacitors, which are intended to be effective at lower frequencies, the current return path distance is less critical.

## Input Capacitance

Along with bypassing and ground, high speed amplifiers can be sensitive to parasitic capacitance between the inputs and ground. A few pF of capacitance will reduce the input impedance at high frequencies, in turn increasing the amplifiers' gain, causing peaking of the frequency response, or even oscillations if severe enough. It is recommended that the external passive components that are connected to the input pins be placed as close as possible to the inputs to avoid parasitic capacitance. The ground and power planes must be kept at a distance of at least 0.05 mm from the input pins on all layers of the board.

## Output Capacitance

To a lesser extent, parasitic capacitances on the output can cause peaking of the frequency response. There are two methods to minimize this effect.

1. Put a small value resistor in series with the output to isolate the load capacitor from the amp's output stage; see TPCs 7, 8,22 , and 23.
2. Increase the phase margin with higher noise gains or add a pole with a parallel resistor and capacitor from -IN to the output.

## Input-to-Output Coupling

The input and output signal traces should not be parallel to minimize capacitive coupling between the inputs and outputs, avoiding any positive feedback.

## APPLICATIONS

Low Power ADC Driver

Figure 3. Schematic to Drive AD9203 with the AD8039

## Differential A/D Driver

The AD9203 is a low power ( 125 mW on a 5 V supply) 40 MSPS 10-bit converter. This represents a breakthrough in power/speed for ADCs. As such, the low power, high performance AD8039 is an appropriate choice of amplifier to drive it.
In low supply voltage applications, differential analog inputs are needed to increase the dynamic range of the ADC inputs. Differential driving can also reduce second and other even-order distortion products. The AD8039 can be used to make a dc-coupled, single-ended-to-differential driver for one of these ADCs. Figure 3 is a schematic of such a circuit for driving an AD9203, a 10-bit, 40 MSPS ADC.

## AD8038/AD8039

The AD9203 works best when the common-mode voltage at the input is at the midsupply or 2.5 V . The output stage design of the AD8039 makes it ideal for driving these types of ADCs.
In this circuit, one of the op amps is configured in the inverting mode, while the other is in the noninverting mode. However, to provide better bandwidth matching, each op amp is configured for a noise gain of +2 . The inverting op amp is configured for a gain of -1 , while the noninverting op amp is configured for a gain of +2 . Each has a very similar ac response. The input signal to the noninverting op amp is divided by 2 to normalize its voltage level and make it equal to the inverting output.
The outputs of the op amps are centered at 2.5 V , which is the midsupply level of the ADC. This is accomplished by first taking the 2.5 V reference output of the ADC and dividing it by 2 with a pair of $1 \mathrm{k} \Omega$ resistors. The resulting 1.25 V is applied to each op amp's positive input. This voltage is then multiplied by the gain of the op amps to provide a 2.5 V level at each output.

## Low Power Active Video Filter

Some composite video signals derived from a digital source contain clock feedthrough that can limit picture quality. Active filters made from op amps can be used in this application, but they will consume 25 mW to 30 mW for each channel. In power-sensitive applications, this can be too much, requiring the use of passive filters that can create impedance matching problems when driving any significant load.
The AD8038 can be used to make an effective low-pass active filter that consumes one-fifth of the power consumed by an active filter made from an op amp. Figure 4 shows a circuit that uses an AD 8038 to create a single $\pm 2.5 \mathrm{~V}$ supply, three-pole Sallen-Key filter. This circuit uses a single RC pole in front of a standard two-pole active section.

Figure 4. Low-Pass Filter for Video
Figure 5 shows the frequency response of this filter. The response is down 3 dB at 6 MHz , so it passes the video band with little attenuation. The rejection at 27 MHz is 45 dB , which provides more than a factor of 100 in suppression of the clock components at this frequency.

Figure 5. Video Filter Response

## OUTLINE DIMENSIONS

Dimensions shown in millimeters and (inches)
8-Lead Plastic SOIC
(R-8)

CONTROLLING DIMENSIONS ARE IN MILLIMETERS; INCH DIMENSIONS (IN PARENTHESES) ARE ROUNDED-OFF MILLIMETER EQUIVALENTS FOR REFERENCE ONLY AND ARE NOT APPROPRIATE FOR USE IN DESIGN
COMPLIANT TO JEDEC STANDARDS MS-012 AA

## AD8038/AD8039 <br> Revision History

Location Page
5/02-Data Sheet changed from REV. A to REV. B.
Add part number AD8038 ..... UNIVERSAL
Changes to Product Title ..... 1
Changes to FEATURES ..... 1
Changes to PRODUCT DESCRIPTION ..... 1
Changes to CONNECTION DIAGRAM ..... 1
Update to SPECIFICATIONS ..... 2
Update to MAXIMUM POWER DISSIPATION ..... 4
Update to OUTPUT SHORT CIRCUIT ..... 4
Update to ORDERING GUIDE ..... 4
Change to FIGURE 2 ..... 4
Change to TPC 2 ..... 5
Change to TPC 18 ..... 6
Change to TPC 27 ..... 7
Change to TPC 29 ..... 8
Change to TPC 30 ..... 8
Change to TPC 31 ..... 8
Added TPC 36 ..... 8
Added TPC 37 ..... 9
Edits to Low Power Active Video Filter ..... 10
Change to Figure 4 ..... 10
Data Sheet changed from REV. 0 to REV. A.
Changes to FEATURES ..... 1
Update SPECIFICATIONS ..... 2, 3
Edits to TPC 19 ..... 7
