## DESCRIPTION

January 2001

The LTC ${ }^{\circledR} 1799$ is a precision oscillator that is easy to use and occupies very little PC board space．The oscillator frequency is programmed by a single external resistor （ $\mathrm{R}_{\text {SET }}$ ）．The LTC1799 has been designed for high accuracy operation（ $\leq 1.5 \%$ frequency error）without the need for external trim components．
The LTC1799 operates with a single 2.7 V to 5.5 V power supply and provides a rail－to－rail， $50 \%$ duty cycle square wave output．The CMOS output driver ensures fast rise／fall times and rail－to－rail switching．The frequency－setting resistor can vary from 3.32 k to 1 M to select a master oscillator frequency between 100 kHz and $30 \mathrm{MHz}(5 \mathrm{~V}$ supply）．The three－state DIV input determines whether the master clock is divided by 1,10 or 100 before driving the output，providing three frequency ranges spanning 1 kHz to 30 MHz （5V supply）．The LTC1799 features a proprietary feedback loop that linearizes the relationship between RSET and frequency，eliminating the need for tables to calculate frequency．The oscillator can be easily pro－ grammed using the simple formula outlined below：
$f_{\text {OSC }}=10 \mathrm{MHz} \bullet\left(\frac{10 \mathrm{k}}{\mathrm{N} \bullet \mathrm{R}_{\text {SET }}}\right), N= \begin{cases}100, & \text { DIV PIN }=\mathrm{V}^{+} \\ 10, & \text { DIV PIN }=\mathrm{Hi}-\mathrm{Z} \\ 1, & \text { DIV PIN }=\text { GND }\end{cases}$
$\overline{\boldsymbol{\Sigma}}$ ，LTC and LT are registered trademarks of Linear Technology Corporation．

Note 1: Absolute Maximum Ratings are those values beyond which the life of the device may be impaired.
Note 2: Frequencies near 100 kHz and 1 MHz may be generated using two different values of RSET (see the Table 1 in the Applications Information section). For these frequencies, the error is specified under the following assumption: 10 k < $\mathrm{R}_{\text {SET }} \leq 100 \mathrm{k}$.
Note 3: Frequency error (defined as the deviation from the fosc equation) includes drift over temperature and over supply.

Note 4: Jitter is the ratio of the peak-to-peak distribution of the period to the mean of the period. This specification is based on characterization and is not $100 \%$ tested.
Note 5: Output rise and fall times are measured between the 10\% and $90 \%$ power supply levels. These specifications are based on characterization.

## PIn functions

$\mathrm{V}^{+}$(Pin 1 ): Voltage Supply ( $2.7 \mathrm{~V} \leq \mathrm{V}^{+} \leq 5.5 \mathrm{~V}$ ). This supply must be kept free from noise and ripple. It should be bypassed directly to a ground plane.
GND (Pin 2): Ground. Should be tied to a ground plane for best performance.

SET (Pin 3): Frequency-Setting Resistor Input. The value of the resistor connected between this pin and $\mathrm{V}^{+}$determines the oscillator frequency. The voltage on this pin is held by the LTC1799 to approximately 1.1 V below the $\mathrm{V}^{+}$ voltage. For best performance, use a precision metal film resistor with a value between 10k and 200k and limit the capacitance on this pin to less than $2 p F$.

DIV (Pin 4): Divider-Setting Input. This three-state input selects among three divider settings, determining the value of $N$ in the frequency equation. Pin 4 should be tied
to GND for the $\div 1$ setting, the highest frequency range. Floating Pin 4 divides the master oscillator by 10. Pin 4 should be tied to $\mathrm{V}^{+}$for the $\div 100$ setting, the lowest frequency range. To detect a floating DIV pin, the LTC1799 attempts to pull the pin toward midsupply. Therefore, driving the DIV pin high requires sourcing approximately $5 \mu \mathrm{~A}$. Likewise, driving DIV low requires sinking $5 \mu \mathrm{~A}$. When floated, the DIV pin will be held near midsupply by these current sources. When it is floated, it is recommended that the DIV pin be bypassed by a 1 nF capacitor or surrounded by a ground shield to prevent excessive coupling from other PCB traces.
OUT (Pin 5): Oscillator Output. This pin can easily drive $5 \mathrm{k} \Omega$ or 10 pF loads. Larger loads may cause inaccuracies due to supply bounce at high frequencies.

## LTC1799

## APPLICATIONS INFORMATION

Selecting the Divider Setting and Resistor

The LTC1799's master oscillator has a frequency range spanning 0.1 MHz to 30 MHz . However, accuracy may suffer if the master oscillator is operated at greater than 10 MHz with a supply voltage lower than 4 V . A programmable divider extends the frequency range to greater than three decades. Table 1 describes the recommended frequencies for each divider setting. Note that the ranges overlap; at some frequencies there are two divider/resistor combinations that result in the desired frequency.
In general, any given oscillator frequency ( $f_{\text {Osc }}$ ) should be obtained using the lowest master oscillator frequency. Lower master oscillator frequencies use less power and are more accuate. For instance, $\mathrm{f}_{\text {Osc }}=100 \mathrm{kHz}$ can be obtained by either $R_{S E T}=10 \mathrm{k}, \mathrm{N}=100$, master oscillator $=10 \mathrm{MHz}$ or $\mathrm{R}_{\text {SET }}=100 \mathrm{k}, \mathrm{N}=10$, master oscillator $=1 \mathrm{MHz}$. The $\mathrm{R}_{\text {SET }}=100 \mathrm{k}$ is preferred for lower power and better accuracy.

Table 1. Frequency Range vs Divider Setting

| DIVIDER SETTING |  | FREQUENCY RANGE |
| :--- | :---: | :---: |
| $\div 1 \Rightarrow$ DIV (Pin 4) $=$ GND |  |  |
| $\div 10 \Rightarrow \quad$ DIV (Pin 4) $=$ Floating |  |  |
| $\div 100 \Rightarrow \quad$ DIV (Pin 4) $=V^{+}$ |  |  |
| $\div \mathrm{kHz}$ to 1 MHz |  |  |

*At master oscillator frequencies greater than $10 \mathrm{MHz}(\mathrm{RSET}<10 \mathrm{k} \Omega$ ), the LTC1799 may suffer reduced accuracy with a supply voltage less than 4 V .
After choosing the proper divider setting, determine the correct frequency-setting resistor. Because of the linear correspondence between oscillation period and resistance, a simple equation relates resistance with frequency.

$$
\begin{aligned}
& \mathrm{R}_{\text {SET }}=10 \mathrm{k} \bullet\left[10 \mathrm{MHz} /\left(\mathrm{N} \bullet \mathrm{f}_{\mathrm{OS}}\right)\right], \mathrm{N}=1,10,100 \\
& \left(\mathrm{R}_{\text {SETMIN }}=3.32 \mathrm{k}(5 \mathrm{~V} \text { Supply), } 5 \mathrm{k}(3 \mathrm{~V} \text { Supply), }\right. \\
& \left.\mathrm{R}_{\text {SETMAX }}=1 \mathrm{M}\right)
\end{aligned}
$$

Any resistor, $\mathrm{R}_{\text {SET }}$, tolerance adds to the inaccuracy of the oscillator, fosc.

## Settling Time

The settling time is proportional to $\mathrm{R}_{\text {SET }}$ and is approximately $\mathrm{t}_{\text {SETTLE }} \approx \mathrm{R}_{\text {SET }} \cdot(5 \mu \mathrm{~S} / \mathrm{k} \Omega)$. This parameter is guaranteed by design and not $100 \%$ tested.
