AM447

#### **FEATURES**

- Very Low Offset Voltage: < 25μV</li>
- Low Input Bias Current: ≤ 5nA
- High Input Sensitivity
- High CMRR: > 90dB min
- Wide Operating Temperature Range: -40°C...+140°C
- Adjustable Rail-to-Rail Voltage Output Stage: 0.5...4.5V
- Single Supply Device (ratiometric)
- Integrated Source and Sink Capability: ±2mA
- Low Noise Behaviour

### **APPLICATIONS**

- Small Signal (Bridge) Amplifier
  Low Pressure Sensors
  Automotive Applications
  DMS Interface
  Interface for Ceramic Sensors
- High Precision Amplifier
  Medical Instrumentation
  Data Acquisition

### **GENERAL DESCRIPTION**

The AM447 is a high precision amplifier, designed for amplification of sensor bridge signals up to 35mV full scale. The single supply circuit consists of a high precision instrumentation amplifier (IA) and an integrated ratiometric output stage. Input offset voltages less than  $\pm 25\mu V$  ( $\pm 1\mu V/^{\circ}C$ ) are adjustable by only two externally trimmable resistors. The monitoring of the amplified signal is possible at the output of the IA and makes the adjustment easier. With the externally adjustable gain of the output stage, the AM447 can be used for different signal sources. The 2mA sink and source capability makes it ideal for high precision applications specially in the field of automotive sensors.

### DELIVERY

- DIL16 packages (samples, small quantities)
- SO16(n) packages
- Dice on 5" blue foil

**ESD:** This integrated circuit can be damaged by ESD. Analog Microelectronics recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage. ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

Notes: <sup>1)</sup> The offset adjustment is described in the *Functional Description*. An offset compensation over temperature can only be achieved by choosing the resistors  $R_{OC1}$  and  $R_{OC2}$  with the same temperature coefficient and a very close placement of them in the circuit.

<sup>2)</sup> A good matching of the resistor  $R_{SET}$  with the bridge resistors is forced.

 $^{3)}$  The symmetry of the two resistor half bridges has to be better than 2%.

### **FUNCTIONAL DESCRIPTION**

The IC AM447 is an integrated high precision amplifier for low bridge output signals. Basically the AM447 is composed of 2 functional sections as shown in Figure 1:

1. A high accuracy *instrumentation amplifier (IA)* allows amplification with a high signal-to-noise ratio. The two offset compensation resistors  $R_{OC1}$  and  $R_{OC2}$  offer the possibility to make the input offset voltage of the instrumentation amplifier to nearly zero. But offset compensation over temperature is only given if the resistors  $R_{OC1}$  and  $R_{OC2}$  have the same temperature coefficients. Furthermore, these resistors have to be placed together very close. It is also necessary to use similar metals for the connection of the sensor bridge and the AM447 to avoid thermocouple effects. The internal gain of the IA is fixed to the value  $G_{INT} = 102$ . The output voltage  $V_{IAOUT}$  (pin 10) of the IA is given by the following equation:

 $V_{IAOUT} = G_{INT} \cdot (V_{IN+} - V_{IN-}) + V_{VREF}$ 

2. An *output stage* de–couples the IA and thus improves the performance of the AM447. The gain factor *G* is fixed by the two external resistors  $R_{G1}$  and  $R_{G2}$ . The gain factor of the output stage is defined by

$$G_{ADJ} = 1 + \frac{R_{G2}}{R_{G1}}$$

The output signal  $V_{OUT}$  (pin 10) can be calculated with

$$V_{OUT} = G\left(V_{IN+} - V_{IN-}\right) + V_{VREF} = \underbrace{G_{INT} \cdot G_{ADJ}\left(V_{IN+} - V_{IN-}\right)}_{\text{Span adjustment}} + \underbrace{V_{VREF}}_{\substack{VREF}}_{\substack{VREF}}$$

The AM447 is suited for two types of transducers. The IC is designed for usage with noncompensated and non-calibrated sensors using resistors  $R_1$  and  $R_2$  for offset calibration as well as for sensor systems with calibrated transducers. The remaining offset of the transducers can be calibrated by variation of  $V_{VREF}$ . The adjustment of the offset is then:

$$V_{VREF} = \frac{R_{O2}}{R_{O1} + R_{O2}} V_{CC}$$

The entire sensor systems realised with the different types of AM447 and only a few external components are shown in Figures 2 and 3.

#### Offset calibration of the instrumentation amplifier

The offset compensation has to be handled with care because the entire system performance depends on it. Please note, that this offset adjustment doesn't include the bridge offset.

The offset compensation has to be done in the following order:

- $T = 25^{\circ}$ C and  $V_{cc} = 5$ V
- $V_{IN+} = V_{IN-} = V_{REF} = 2.5 \text{ V}$
- The voltage between  $V_{IAOUT}$  (pin 12) and  $V_{REF}$  (pin 6) has to be adjusted to zero Volt.
- $V_{IAOUT}$  is increased by increasing  $R_{OC1}$  and is decreased by increasing  $R_{OC2}$ .

### **DELIVERY**

The AM447 is available in version:

- 16 pin DIL packages (samples)
- SO 16 (n) packages
- Dice on 5" blue foil
